Secondary Definition of COVID-19* Starting 14 Days After Second Injection		
Number of Events	807	58
Vaccine Efficacy Based on Hazard Ratio (95% CI) [1]		0.934 (0.914, 0.949)
Death Caused by COVID-19 Starting 14 Days After Second Injection		
Number of Events	3	0
Vaccine Efficacy Based on Hazard Ratio (95% CI) [1]		1.000 (NE, 1.000)

* with the censoring rules for efficacy analyses. COVID-19 case is based on eligible symptoms and positive RT-PCR within 14 days. If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys.

[1] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor. For asymptomatic SARS-CoV-2 infection, VE and 95% CI are estimated using Fine and Gray's sub-distribution hazard model with disease cases as competing events and with the treatment group as a covariate, adjusting for stratification factor.

[2] 1-sided p-value from stratified Cox proportional hazard model to test the null hypothesis VE <= 0.3.

[3] Including participant decision visit.

[4] n and N are based on the number of subjects in the Full Analysis Set.

[1] Incidence rate for each time period is defined as the number of subjects with an event during the time period divided by the number of subjects at risk at the beginning of each time period and adjusted by person-years (total time at risk) in each treatment group. Person-years for each time period is defined as the total years from randomization date to the date of COVID-19, the date of earliest positive RT-PCR or Elecsys at scheduled visits, the end of each time period, last date of study participation, or efficacy data cutoff date, whichever is the earliest. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

[2] VE is defined as 1 − ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years for the time period.

Program Path: \\wilbtia\wilbtia01\Moderna MODMRNA1273P301_U\BLA\TLF\t1402010102010501.sas 10JUN2021 14:34

* with the censoring rules for efficacy analyses. COVID-19 case is based on eligible symptoms and positive RT-PCR within 14 days. If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys.

[1] Incidence rate for each time period is defined as the number of subjects with an event during the time period divided by the number of subjects at risk at the beginning of each time period and adjusted by person-years (total time at risk) in each treatment group. Person-years for each time period is defined as the total years from randomization date to the date of COVID-19, the date of earliest positive RT-PCR or Elecsys at scheduled visits, the end of each time period, last date of study participation, or efficacy data cutoff date, whichever is the earliest. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

[2] VE is defined as 1 − ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years for the time period.

[1] Include cases that occurred in the blinded phase and not include cases that occurred in the open-label phase.
[2] Include cases that occurred at participant decision visit (PDV) before or on efficacy data cutoff date. If a subject has positive RT-PCR test or Elecsys anti-SARS-CoV-2 assay on the same date for both PDV and another scheduled visit, the subject is counted under PDV.

Number of Subjects with COVID-19*, n (%)	744 (5.3)	55 (0.4)
Number of Subjects Censored, n (%)	13420 (94.7)	14232 (99.6)
Vaccine Efficacy Based on Hazard Ratio (95% CI) [1]		0.932 (0.910, 0.948)
p-value [2]		<.0001
Person-Years [3]	5445.2	5729.9
Incidence Rate per 1,000 Person-Years (95% CI) [4]	136.633 (126.991, 146.814)	9.599 (7.231, 12.494)
Vaccine Efficacy Based on Incidence Rate (95% CI) [5]		0.930 (0.908, 0.948)

* with the censoring rules for efficacy analyses. COVID-19 case is based on eligible symptoms and positive RT-PCR within 14 days. If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys.

[1] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor.

[2] 1-sided p-value from stratified Cox proportional hazard model to test the null hypothesis VE <= 0.3.

[3] Person-years is defined as the total years from randomization date to the date of COVID-19, the date of earliest positive RT-PCR or Elecsys at scheduled visits, last date of study participation, or efficacy data cutoff date, whichever is earlier.

[4] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

[5] VE is defined as 1 — ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years.

If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys.

[1] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor.

[2] Person-years is defined as the total years from randomization date to the date of COVID-19, the date of earliest positive RT-PCR or Elecsys at scheduled visits, last date of study participation, or efficacy data cutoff date, whichever is earlier.

[3] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

[4] VE is defined as 1 - ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years.

Person-Years [2]	4179.9	4388.9
Incidence Rate per 1,000 Person-Years (95% CI) [3]	155.746 (144.010, 168.183)	11.165 (8.260, 14.760)
Vaccine Efficacy Based on Incidence Rate (95% CI) [4]		0.928 (0.904, 0.948)

* with the censoring rules for efficacy analyses. COVID-19 case is based on eligible symptoms and positive RT-PCR within 14 days. If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys.

[1] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor if applicable.

[2] Person-years is defined as the total years from randomization date to the date of COVID-19, the date of earliest positive RT-PCR or Elecsys at scheduled visits, last date of study participation, or efficacy data cutoff date, whichever is earlier.

[3] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

[4] VE is defined as 1 - ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years.

If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys.

[1] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor if applicable.

[2] Person-years is defined as the total years from randomization date to the date of COVID-19, the date of earliest positive RT-PCR or Elecsys at scheduled visits, last date of study participation, or efficacy data cutoff date, whichever is earlier.

[3] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

[4] VE is defined as 1 — ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years.

If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys.

[1] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor if applicable.

[2] Person-years is defined as the total years from randomization date to the date of COVID-19, the date of earliest positive RT-PCR or Elecsys at scheduled visits, last date of study participation, or efficacy data cutoff date, whichever is earlier.

[3] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

[4] VE is defined as 1 — ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years.

If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys.

[1] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor if applicable.

[2] Person-years is defined as the total years from randomization date to the date of COVID-19, the date of earliest positive RT-PCR or Elecsys at scheduled visits, last date of study participation, or efficacy data cutoff date, whichever is earlier.

[3] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

[4] VE is defined as 1 — ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years.

Vaccine Efficacy Based on Incidence Rate (95% CI) [4]		0.868 (0.626, 0.966)

* with the censoring rules for efficacy analyses. COVID-19 case is based on eligible symptoms and positive RT-PCR within 14 days. If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys.

[1] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor if applicable.

[2] Person-years is defined as the total years from randomization date to the date of COVID-19, the date of earliest positive RT-PCR or Elecsys at scheduled visits, last date of study participation, or efficacy data cutoff date, whichever is earlier.

[3] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

[4] VE is defined as 1 — ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years.

* with the censoring rules for efficacy analyses. COVID-19 case is based on eligible symptoms and positive RT-PCR within 14 days. If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys.

[1] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor if applicable.

[2] Person-years is defined as the total years from randomization date to the date of COVID-19, the date of earliest positive RT-PCR or Elecsys at scheduled visits, last date of study participation, or efficacy data cutoff date, whichever is earlier.

[3] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

[4] VE is defined as 1 - ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years.

Minority is defined as Blacks or African Americans, Hispanics or Latinos, American Indians or Alaska Natives, Native Hawaiians, and other Pacific Islanders, and Non-Minority includes all the others whose race or ethnicity is not unknown, unreported or missing.
[1] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor if applicable.
[2] Person-years is defined as the total years from randomization date to the date of COVID-19, the date of earliest positive RT-PCR or Elecsys at scheduled visits, last date of study participation, or efficacy data cutoff date, whichever is earlier.
[3] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.
[4] VE is defined as 1 - ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years.

[1] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate.

[2] Person-years is defined as the total years from randomization date to the date of COVID-19, the date of earliest positive RT-PCR or Elecsys at scheduled visits, last date of study participation, or efficacy data cutoff date, whichever is earlier.

[3] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

[4] VE is defined as 1 — ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years.

Vaccine Efficacy Based on Incidence Rate (95% CI) [4]		0.934 (0.740, 0.992)

* with the censoring rules for efficacy analyses. COVID-19 case is based on eligible symptoms and positive RT-PCR within 14 days. If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys.

[1] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor if applicable.

[2] Person-years is defined as the total years from randomization date to the date of COVID-19, the date of earliest positive RT-PCR or Elecsys at scheduled visits, last date of study participation, or efficacy data cutoff date, whichever is earlier.

[3] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

[4] VE is defined as 1 - ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years.

Person-Years [2]	251.0	240.2
Incidence Rate per 1,000 Person-Years (95% CI) [3]	59.767 (33.451, 98.576)	0.000 (NE, 15.355)
Vaccine Efficacy Based on Incidence Rate (95% CI) [4]		1.000 (0.709, NE)

* with the censoring rules for efficacy analyses. COVID-19 case is based on eligible symptoms and positive RT-PCR within 14 days. If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys.

[1] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor if applicable.

[2] Person-years is defined as the total years from randomization date to the date of COVID-19, the date of earliest positive RT-PCR or Elecsys at scheduled visits, last date of study participation, or efficacy data cutoff date, whichever is earlier.

[3] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

[4] VE is defined as 1 — ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years.

* with the censoring rules for efficacy analyses. COVID-19 case is based on eligible symptoms and positive RT-PCR within 14 days. If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys. Severe COVID-19 case is defined based on COVID-19 case.

[1] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor if applicable.

[2] Person-years is defined as the total years from randomization date to the date of severe COVID-19, the date of earliest positive RT-PCR or Elecsys at scheduled visits, last date of study participation, or efficacy data cutoff date, whichever is earlier.

[3] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

[4] VE is defined as 1 - ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years.

* with the censoring rules for efficacy analyses. COVID-19 case is based on eligible symptoms and positive RT-PCR within 14 days. If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys. Severe COVID-19 case is defined based on COVID-19 case.

[1] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor if applicable.

[2] Person-years is defined as the total years from randomization date to the date of severe COVID-19, the date of earliest positive RT-PCR or Elecsys at scheduled visits, last date of study participation, or efficacy data cutoff date, whichever is earlier.

[3] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

[4] VE is defined as 1 — ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years.

Subgroup Analysis of Vaccine Efficacy of mRNA-1273 to Prevent Severe COVID-19* Based on Adjudication Committee Assessments Starting 14 Days After Second Injection by Risk for Severe COVID-19 at Screening
Per-Protocol Set

Risk for Severe COVID-19 at Screening: At Least Two Risk Factors

	Placebo (N=602)	mRNA-1273 (N=623)
Number of Subjects with Severe COVID-19*, n (%)	12 (2.0)	0
Number of Subjects Censored, n (%)	590 (98.0)	623 (100)
Vaccine Efficacy Based on Hazard Ratio (95% CI) [1]		1.000 (NE, 1.000)
Person-Years [2]	241.0	251.8
Incidence Rate per 1,000 Person-Years (95% CI) [3]	49.785 (25.725, 86.964)	0.000 (NE, 14.651)
Vaccine Efficacy Based on Incidence Rate (95% CI) [4]		1.000 (0.655, NE)

* with the censoring rules for efficacy analyses. COVID-19 case is based on eligible symptoms and positive RT-PCR within 14 days. If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys. Severe COVID-19 case is defined based on COVID-19 case.

[1] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor if applicable.

[2] Person-years is defined as the total years from randomization date to the date of severe COVID-19, the date of earliest positive RT-PCR or Elecsys at scheduled visits, last date of study participation, or efficacy data cutoff date, whichever is earlier.

[3] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

[4] VE is defined as 1 — ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years.

If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys. Severe COVID-19 case is defined based on COVID-19 case.

[1] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor if applicable.

[2] Person-years is defined as the total years from randomization date to the date of severe COVID-19, the date of earliest positive RT-PCR or Elecsys at scheduled visits, last date of study participation, or efficacy data cutoff date, whichever is earlier.

[3] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

[4] VE is defined as 1 - ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years.

Vaccine Efficacy Based on Incidence Rate (95% CI) [4]		0.558 (-1.471, 0.956)

* with the censoring rules for efficacy analyses. COVID-19 case is based on eligible symptoms and positive RT-PCR within 14 days. If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys. Severe COVID-19 case is defined based on COVID-19 case.

[1] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor.

[2] Person-years is defined as the total years from randomization date to the date of severe COVID-19, the date of earliest positive RT-PCR or Elecsys at scheduled visits, last date of study participation, or efficacy data cutoff date, whichever is earlier.

[3] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

[4] VE is defined as 1 - ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years.

Incidence Rate per 1,000 Person-Years (95% CI) [3]	145.930 (136.088, 156.296)	10.406 (7.960, 13.367)
Vaccine Efficacy Based on Incidence Rate (95% CI) [4]		0.929 (0.907, 0.946)

* with the censoring rules for efficacy analyses. COVID-19 case is based on eligible symptoms and positive RT-PCR within 14 days. If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys.

[1] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor.

[2] Person-years is defined as the total years from randomization date to the date of secondary definition of COVID-19, the date of earliest positive RT-PCR or Elecsys at scheduled visits, last date of study participation, or efficacy data cutoff date, whichever is earlier.

[3] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

[4] VE is defined as 1 — ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years.

* with the censoring rules for efficacy analyses. COVID-19 case is based on eligible symptoms and positive RT-PCR within 14 days. If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys.

[1] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor.

[2] Person-years is defined as the total years from randomization date to the date of COVID-19, the date of earliest positive RT-PCR or Elecsys at scheduled visits, last date of study participation, or efficacy data cutoff date, whichever is earlier.

[3] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

[4] VE is defined as 1 — ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years.

BOI = Burden of Infection.
BOI is defined based on asymptomatic infection and adjudicated COVID-19 cases. BOI score: 0 = No infection, 1/2 = Asymptomatic infection, 1 = COVID-19 without hospitalization, 2 = COVID-19 with hospitalization, 3 = Death.
[1] Number of subjects who are without SARS-CoV-2 infection at the beginning of each follow up period and have available data in each follow up period. Percentages are based on number of subjects with BOI score.
[2] The maximum BOI score during the follow up period.
[3] Includes infection and COVID-19 cases occurred after month 2 through month 7 or participant decision visit or unblinding date whichever is earlier, with hospitalization and death are up to 28 days after COVID-19 onset date.

BOI = Burden of Infection.
BOI is defined based on asymptomatic infection and adjudicated COVID-19 cases. BOI score: 0 = No infection, 1/2 = Asymptomatic infection, 1 = COVID-19 without hospitalization, 2 = COVID-19 with hospitalization, 3 = Death.
[1] Number of subjects who are with SARS-CoV-2 infection at the beginning of each period or anytime during each period. Percentages are based on number of subjects with BOI score in the period.
[2] The maximum BOI score during the follow up period.
[3] Includes infection and COVID-19 cases occurred after month 2 through month 7 or participant decision visit or unblinding date whichever is earlier, with hospitalization and death are up to 28 days after COVID-19 onset date.

Incidence Rate per 1,000 Person-Years (95% CI) [3]	2.755 (1.542, 4.543)	0.524 (0.108, 1.530)

*COVID-19 cases with Lineage other than B.1.427 or B.1.429 are considered as competing events
[1] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using Fine and Gray's sub-distribution hazard model with disease cases as competing events and with the treatment group as a covariate, adjusting for stratification factor.
[2] Person-years is defined as the total years from randomization date to the earliest of the date of symptomatic SARS-CoV-2 infection, the date of asymptomatic SARS-CoV-2 infection, last date of study participation, or efficacy data cutoff date, whichever is earlier.
[3] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

Table 14.2.4.1.1.1.3.1
Summary of Binding Antibody Specific to SARS-CoV-2 Spike Protein by MSD by Baseline SARS-CoV-2 Status
Per-Protocol Random Subcohort for Immunogenicity

CI = confidence interval, GM = geometric mean, MSD = meso scale discovery.
N1 = Number of subjects with non-missing data at baseline and the corresponding timepoint.
Antibody values reported as below the lower limit of quantification (LLOQ) are replaced by 0.5 x LLOQ. Values greater than the upper limit of quantification (ULOQ) are replaced by the ULOQ if actual values are not available.
[1] Number of subjects with non-missing data at the corresponding timepoint.
[2] 95% CI is calculated based on the t-distribution of the log-transformed values or the difference in the log-transformed values for GM value and GM fold-rise, respectively, then back transformed to the original scale for presentation.
[3] Seroresponse at a subject level is defined as a change from below the LLOQ to equal or above the LLOQ, or at least a 1.9-fold rise if baseline is equal to or above the LLOQ.
[4] Number of subjects meeting the criterion at the time point. Percentages are based on N1.
[5] 95% CI is calculated using the Clopper-Pearson method.
[6] >= z-fold increase from baseline at participant level is defined as a >= z x LLOQ for participants with baseline antibody level below the LLOQ, or a z-times or higher level ratio in participants with baseline antibody level equal to or above the LLOQ.

Table 14.2.4.1.1.1.4.1
Summary of Binding Antibody Specific to SARS-CoV-2 Spike Protein by MSD by Baseline SARS-CoV-2 Status and Age Group
Per-Protocol Random Subcohort for Immunogenicity

CI = confidence interval, GM = geometric mean, MSD = meso scale discovery.
N1 = Number of subjects with non-missing data at baseline and the corresponding timepoint.
Antibody values reported as below the lower limit of quantification (LLOQ) are replaced by 0.5 x LLOQ. Values greater than the upper limit of quantification (ULOQ) are replaced by the ULOQ if actual values are not available.
[1] Number of subjects with non-missing data at the corresponding timepoint.
[2] 95% CI is calculated based on the t-distribution of the log-transformed values or the difference in the log-transformed values for GM value and GM fold-rise, respectively, then back transformed to the original scale for presentation.
[3] Seroresponse at a subject level is defined as a change from below the LLOQ to equal or above the LLOQ, or at least a 1.9-fold rise if baseline is equal to or above the LLOQ.
[4] Number of subjects meeting the criterion at the time point. Percentages are based on N1.
[5] 95% CI is calculated using the Clopper-Pearson method.
[6] >= z-fold increase from baseline at participant level is defined as a >= z x LLOQ for participants with baseline antibody level below the LLOQ, or a z-times or higher level ratio in participants with baseline antibody level equal to or above the LLOQ.

Table 14.2.4.1.1.2.3.1
MMRM Analysis of Binding Antibody Specific to SARS-CoV-2 Spike Protein by MSD by Baseline SARS-CoV-2 Status
Per-Protocol Random Subcohort for Immunogenicity

Baseline SARS-CoV-2 Status: Negative
Antibody: SARSCOV2S2P IgG Antibody (AU/mL) by MSD MULTIPLEX (LLOQ: 199.64, ULOQ: 1128438.87)

Timepoint Data Category Statistic	Placebo (N=142)	mRNA-1273 (N=1055)
Day 29		
n	139	1040
N1	137	1033
GLSM	120.458	35916.422
95% CI	101.105, 143.515	33687.886, 38292.381
mRNA-1273 vs. Placebo		
Ratio of GLSM		298.17
95% CI		247.44, 359.29

CI = confidence interval, GLSM = geometric least squares mean, MSD = meso scale discovery.
n = Number of subjects with non-missing data at the corresponding timepoint. N1 = Number of subjects with non-missing data at baseline and the corresponding timepoint.
Antibody values reported as below the lower limit of quantification (LLOQ) are replaced by 0.5 x LLOQ. Values greater than the upper limit of quantification (ULOQ) are replaced by the ULOQ if actual values are not available.
The GLSM, ratio of GLSM, and corresponding 95% confidence intervals (CI) are estimated using a restricted maximum likelihood-based linear mixed effects model, including all available log-transformed binding antibody levels at each post-baseline visit as the dependent variable, treatment group, visit, and interaction of treatment group and visit as fixed effects, and randomization stratification factor, minority/non-minority, baseline log-transformed value (only for subjects with baseline SARS-CoV-2 positive), and subject as random effects, then back transformed to the original scale for presentation. An unstructured covariance structure is used to model the within-subject errors and the Kenward-Roger method is used to approximate the denominator degrees of freedom.

Table 14.2.4.1.2.1.3.1
Summary of Binding Antibody Specific to SARS-CoV-2 Spike Protein by ELISA by Baseline SARS-CoV-2 Status
Per-Protocol Random Subcohort for Immunogenicity

CI = confidence interval, ELISA = enzyme-linked immunosorbent assay, GM = geometric mean.
N1 = Number of subjects with non-missing data at baseline and the corresponding timepoint.
Antibody values reported as below the lower limit of quantification (LLOQ) are replaced by 0.5 x LLOQ. Values greater than the upper limit of quantification (ULOQ) are replaced by the ULOQ if actual values are not available.
[1] Number of subjects with non-missing data at the corresponding timepoint.
[2] 95% CI is calculated based on the t-distribution of the log-transformed values or the difference in the log-transformed values for GM value and GM fold-rise, respectively, then back transformed to the original scale for presentation.
[3] Seroresponse at a subject level is defined as a change from below the LLOQ to equal or above the LLOQ, or at least a 4.6-fold rise if baseline is equal to or above the LLOQ.
[4] Number of subjects meeting the criterion at the time point. Percentages are based on N1.
[5] 95% CI is calculated using the Clopper-Pearson method.
[6] >= z-fold increase from baseline at participant level is defined as a >= z x LLOQ for participants with baseline antibody level below the LLOQ, or a z-times or higher level ratio in participants with baseline antibody level equal to or above the LLOQ.

Table 14.2.4.1.2.1.4.1
Summary of Binding Antibody Specific to SARS-CoV-2 Spike Protein by ELISA by Baseline SARS-CoV-2 Status and Age Group
Per-Protocol Random Subcohort for Immunogenicity

CI = confidence interval, ELISA = enzyme-linked immunosorbent assay, GM = geometric mean.
N1 = Number of subjects with non-missing data at baseline and the corresponding timepoint.
Antibody values reported as below the lower limit of quantification (LLOQ) are replaced by 0.5 x LLOQ. Values greater than the upper limit of quantification (ULOQ) are replaced by the ULOQ if actual values are not available.
[1] Number of subjects with non-missing data at the corresponding timepoint.
[2] 95% CI is calculated based on the t-distribution of the log-transformed values or the difference in the log-transformed values for GM value and GM fold-rise, respectively, then back transformed to the original scale for presentation.
[3] Seroresponse at a subject level is defined as a change from below the LLOQ to equal or above the LLOQ, or at least a 4.6-fold rise if baseline is equal to or above the LLOQ.
[4] Number of subjects meeting the criterion at the time point. Percentages are based on N1.
[5] 95% CI is calculated using the Clopper-Pearson method.
[6] >= z-fold increase from baseline at participant level is defined as a >= z x LLOQ for participants with baseline antibody level below the LLOQ, or a z-times or higher level ratio in participants with baseline antibody level equal to or above the LLOQ.

Table 14.2.4.1.2.2.3.1
MMRM Analysis of Binding Antibody Specific to SARS-CoV-2 Spike Protein by ELISA by Baseline SARS-CoV-2 Status
Per-Protocol Random Subcohort for Immunogenicity

Baseline SARS-CoV-2 Status: Negative
Antibody: VAC65 Spike IgG Antibody (AU/mL) by ELISA (LLOQ: 1, ULOQ: 2052)

Timepoint Data Category Statistic	Placebo (N=142)	mRNA-1273 (N=1055)
Day 29		
n	141	1055
N1	140	1052
GLSM	0.703	107.195

mRNA-1273 vs. Placebo		
Ratio of GLSM		152.39
95% CI		128.49, 180.73

CI = confidence interval, ELISA = enzyme-linked immunosorbent assay, GLSM = geometric least squares mean.
n = Number of subjects with non-missing data at the corresponding timepoint. N1 = Number of subjects with non-missing data at baseline and the corresponding timepoint.
Antibody values reported as below the lower limit of quantification (LLOQ) are replaced by 0.5 x LLOQ. Values greater than the upper limit of quantification (ULOQ) are replaced by the ULOQ if actual values are not available.
The GLSM, ratio of GLSM, and corresponding 95% confidence intervals (CI) are estimated using a restricted maximum likelihood-based linear mixed effects model, including all available log-transformed binding antibody levels at each post-baseline visit as the dependent variable, treatment group, visit, and interaction of treatment group and visit as fixed effects, and randomization stratification factor, minority/non-minority, baseline log-transformed value (only for subjects with baseline SARS-CoV-2 positive), and subject as random effects, then back transformed to the original scale for presentation. An unstructured covariance structure is used to model the within-subject errors and the Kenward-Roger method is used to approximate the denominator degrees of freedom.

95% CI		(128.71, 180.69)

CI = confidence interval, ELISA = enzyme-linked immunosorbent assay, GLSM = geometric least squares mean, GMR = geometric mean ratio, MSD = meso scale discovery.
n = Number of subjects with non-missing data at the corresponding timepoint. N1 = Number of subjects with non-missing data at baseline and the corresponding timepoint.
Antibody values reported as below the lower limit of quantification (LLOQ) are replaced by 0.5 x LLOQ. Values greater than the upper limit of quantification (ULOQ) are replaced by the ULOQ if actual values are not available.
The log-transformed antibody levels are analyzed using an analysis of covariance (ANCOVA) model with the treatment group as fixed effect and adjusted with randomization stratification factor, minority/non-minority, and baseline log-transformed value (only for subjects with baseline SARS-CoV-2 positive at post-baseline timepoint). The resulted LS means, difference of LS means, and 95% CI are back transformed to the original scale for presentation.

Table 14.2.4.2.1.3.1
Summary of Pseudovirus Neutralizing Antibody ID50 and ID80 Titers by Baseline SARS-CoV-2 Status
Per-Protocol Random Subcohort for Immunogenicity

CI = confidence interval, GM = geometric mean.
N1 = Number of subjects with non-missing data at baseline and the corresponding timepoint.
Antibody values reported as below the lower limit of quantification (LLOQ) are replaced by 0.5 x LLOQ. Values greater than the upper limit of quantification (ULOQ) are replaced by the ULOQ if actual values are not available.
[1] Number of subjects with non-missing data at the corresponding timepoint.
[2] 95% CI is calculated based on the t-distribution of the log-transformed values or the difference in the log-transformed values for GM value and GM fold-rise, respectively, then back transformed to the original scale for presentation.
[3] Seroresponse to pseudovirus neutralizing antibody ID50 titer at a subject level is defined as a change from below the LLOQ to equal or above the LLOQ, or at least a 3.3-fold rise if baseline is equal to or above the LLOQ. Seroresponse to pseudovirus neutralizing antibody ID80 titer at a subject level is defined as a change from below the LLOQ to equal or above the LLOQ, or at least a 2.3-fold rise if baseline is equal to or above the LLOQ.
[4] Number of subjects meeting the criterion at the time point. Percentages are based on N1.
[5] 95% CI is calculated using the Clopper-Pearson method.
[6] >= z-fold increase from baseline at participant level is defined as a >= z x LLOQ for participants with baseline antibody titer below LLOQ, or a z-times or higher titer ratio in participants with baseline antibody titer equal to or above the LLOQ.

Table 14.2.4.2.1.4.1
Summary of Pseudovirus Neutralizing Antibody ID50 and ID80 Titers by Baseline SARS-CoV-2 Status and Age Group
Per-Protocol Random Subcohort for Immunogenicity

CI = confidence interval, GM = geometric mean.
N1 = Number of subjects with non-missing data at baseline and the corresponding timepoint.
Antibody values reported as below the lower limit of quantification (LLOQ) are replaced by 0.5 x LLOQ. Values greater than the upper limit of quantification (ULOQ) are replaced by the ULOQ if actual values are not available.
[1] Number of subjects with non-missing data at the corresponding timepoint.
[2] 95% CI is calculated based on the t-distribution of the log-transformed values or the difference in the log-transformed values for GM value and GM fold-rise, respectively, then back transformed to the original scale for presentation.
[3] Seroresponse to pseudovirus neutralizing antibody ID50 titer at a subject level is defined as a change from below the LLOQ to equal or above the LLOQ, or at least a 3.3-fold rise if baseline is equal to or above the LLOQ. Seroresponse to pseudovirus neutralizing antibody ID80 titer at a subject level is defined as a change from below the LLOQ to equal or above the LLOQ, or at least a 2.3-fold rise if baseline is equal to or above the LLOQ.
[4] Number of subjects meeting the criterion at the time point. Percentages are based on N1.
[5] 95% CI is calculated using the Clopper-Pearson method.
[6] >= z-fold increase from baseline at participant level is defined as a >= z x LLOQ for participants with baseline antibody titer below LLOQ, or a z-times or higher titer ratio in participants with baseline antibody titer equal to or above the LLOQ.

Table 14.2.4.2.2.3.1
MMRM Analysis of Pseudovirus Neutralizing Antibody ID50 and ID80 Titers by Baseline SARS-CoV-2 Status
Per-Protocol Random Subcohort for Immunogenicity

Baseline SARS-CoV-2 Status: Negative
Antibody: Pseudovirus Neutralizing Antibody ID50 Titers (LLOQ: 18.5, ULOQ: 4404)

mRNA-1273 vs. Placebo		
Ratio of GLSM		5.77
95% CI		4.74, 7.02

CI = confidence interval, GLSM = geometric least squares mean.
n = Number of subjects with non-missing data at the corresponding timepoint. N1 = Number of subjects with non-missing data at baseline and the corresponding timepoint.
Antibody values reported as below the lower limit of quantification (LLOQ) are replaced by 0.5 x LLOQ. Values greater than the upper limit of quantification (ULOQ) are replaced by the ULOQ if actual values are not available.
The GLSM, ratio of GLSM, and corresponding 95% confidence intervals (CI) are estimated using a restricted maximum likelihood-based linear mixed effects model, including all available log-transformed neutralizing antibody titers at each post-baseline visit as the dependent variable, treatment group, visit, and interaction of treatment group and visit as fixed effects, and randomization stratification factor, minority/non-minority, baseline log-transformed value (only for subjects with baseline SARS-CoV-2 positive), and subject as random effects, then back transformed to the original scale for presentation. An unstructured covariance structure is used to model the within-subject errors and the Kenward-Roger method is used to approximate the denominator degrees of freedom.

Table 14.2.4.2.3.3.1
ANCOVA Analysis of Pseudovirus Neutralizing Antibody ID50 and ID80 Titers by Baseline SARS-CoV-2 Status
Per-Protocol Random Subcohort for Immunogenicity

CI = confidence interval, GLSM = geometric least squares mean, GMR = geometric mean ratio.
n = Number of subjects with non-missing data at the corresponding timepoint. N1 = Number of subjects with non-missing data at baseline and the corresponding timepoint.
Antibody values reported as below the lower limit of quantification (LLOQ) are replaced by 0.5 x LLOQ. Values greater than the upper limit of quantification (ULOQ) are replaced by the ULOQ if actual values are not available.
The log-transformed antibody titers are analyzed using an analysis of covariance (ANCOVA) model with the treatment group as fixed effect and adjusted with randomization stratification factor, minority/non-minority, and baseline log-transformed value (only for subjects with baseline SARS-CoV-2 positive at post-baseline timepoint). The resulted LS means, difference of LS means, and 95% CI are back transformed to the original scale for presentation.

Antibody: Pseudovirus Neutralizing Antibody ID80 Titers (LLOQ: 14.3, ULOQ: 1295)

Baseline (Day 1)

Percentages are based on the number of subjects with non-missing data at the corresponding timepoint.
Antibody values reported as below the lower limit of quantification (LLOQ) are replaced by 0.5 x LLOQ. Values greater than the upper limit of quantification (ULOQ) are replaced by the ULOQ if actual values are not available.

CI = Confidence intervals. N1 = Number of exposed subjects who submitted any data for the event. Any = Grade 1 or higher.
Percentages are based on the number of exposed subjects who submitted any data for the event (N1).
95% CI is calculated using the Clopper-Pearson method.
Toxicity grade for Erythema (Redness) is defined as: G1 = 25 — 50 mm; G2 = 51 — 100 mm; G3 = > 100 mm. Toxicity grade for Fever is defined as: G1 = 38 — 38.4 C; G2 = 38.5 — 38.9 C; G3 = 39 — 40 C; G4 = > 40 C.

CI = Confidence intervals. N1 = Number of exposed subjects who submitted any data for the event. Any = Grade 1 or higher.
Percentages are based on the number of exposed subjects who submitted any data for the event (N1).
95% CI is calculated using the Clopper-Pearson method.
Toxicity grade for Erythema (Redness) is defined as: G1 = 25 — 50 mm; G2 = 51 — 100 mm; G3 = > 100 mm. Toxicity grade for Fever is defined as: G1 = 38 — 38.4 C; G2 = 38.5 — 38.9 C; G3 = 39 — 40 C; G4 = > 40 C.

CI = Confidence intervals. N1 = Number of exposed subjects who submitted any data for the event. Any = Grade 1 or higher.
Percentages are based on the number of exposed subjects who submitted any data for the event (N1).
95% CI is calculated using the Clopper-Pearson method.
Toxicity grade for Erythema (Redness) is defined as: G1 = 25 — 50 mm; G2 = 51 — 100 mm; G3 = > 100 mm. Toxicity grade for Fever is defined as: G1 = 38 — 38.4 C; G2 = 38.5 — 38.9 C; G3 = 39 — 40 C; G4 = > 40 C.

CI = Confidence intervals. N1 = Number of exposed subjects who submitted any data for the event. Any = Grade 1 or higher.
Percentages are based on the number of exposed subjects who submitted any data for the event (N1).
95% CI is calculated using the Clopper-Pearson method.
Toxicity grade for Erythema (Redness) is defined as: G1 = 25 — 50 mm; G2 = 51 — 100 mm; G3 = > 100 mm. Toxicity grade for Fever is defined as: G1 = 38 — 38.4 C; G2 = 38.5 — 38.9 C; G3 = 39 — 40 C; G4 = > 40 C.

Day 6	69 (0.5)	23 (0.2)	92 (0.3)
Day 7	37 (0.3)	19 (0.1)	56 (0.2)

N1 = Number of exposed subjects who submitted any data for the event.
Percentages are based on the number of exposed subjects who submitted any data for the event (N1).

Table 14.3.1.3.4.2
Summary of Subjects with Grade 3 Solicited Adverse Reactions Within 7 Days After Second Injection by Onset Day
Second Injection Solicited Safety Set

Solicited Adverse Reaction Category Onset Day	Placebo (N=14578) n (%)	mRNA-1273 (N=14691) n (%)	Total (N=29269) n (%)
Solicited Local Adverse Reactions			
Pain - N1	14577	14688	29265
Day 1, 30 Minutes after Vaccination (at Study Clinic)	19 (0.1)	83 (0.6)	102 (0.3)
Day 1, after Vaccination (at Home)	12 (<0.1)	417 (2.8)	429 (1.5)
Day 2	4 (<0.1)	99 (0.7)	103 (0.4)
Day 3	3 (<0.1)	3 (<0.1)	6 (<0.1)
Day 4	0	2 (<0.1)	2 (<0.1)
Day 5	1 (<0.1)	0	1 (<0.1)
Day 6	1 (<0.1)	1 (<0.1)	2 (<0.1)
Day 7	1 (<0.1)	1 (<0.1)	2 (<0.1)
Erythema (Redness) - N1	14577	14687	29264
Day 1, 30 Minutes after Vaccination (at Study Clinic)	3 (<0.1)	0	3 (<0.1)
Day 1, after Vaccination (at Home)	4 (<0.1)	38 (0.3)	42 (0.1)
Day 2	1 (<0.1)	110 (0.7)	111 (0.4)
Day 3	3 (<0.1)	106 (0.7)	109 (0.4)
Day 4	1 (<0.1)	26 (0.2)	27 (<0.1)
Day 5	1 (<0.1)	5 (<0.1)	6 (<0.1)
Day 6	1 (<0.1)	0	1 (<0.1)
Day 7	1 (<0.1)	2 (<0.1)	3 (<0.1)

N1 = Number of exposed subjects who submitted any data for the event.
Percentages are based on the number of exposed subjects who submitted any data for the event (N1).
