FINAL RANDOMIZED BLINDED PHASE (PART A) CLINICAL STUDY REPORT

A Phase 3, Randomized, Stratified, Observer-Blind, Placebo-Controlled Study to Evaluate the Efficacy, Safety, and Immunogenicity of mRNA-1273 SARS-CoV-2 Vaccine in Adults Aged 18 Years and Older

PROTOCOL NUMBER
mRNA-1273-P301

Name of Test Product:	mRNA-1273
Indication:	COVID-19
ClinicalTrials.gov Identifier:	NCT04470427
Sponsor:	ModernaTX, Inc. 200 Technology Square Cambridge, MA 02139
Sponsor Signatory:	Allison August, MD VP, Clinical Development, Infectious Diseases ModernaTX, Inc. Telephone: +1-617-678-8937 E-mail: allison.august@modernatx.com
Drug Development Phase:	3
Study Initiation Date:	First participant first visit: 27 Jul 2020
Part A Analysis Cutoff Date:	Last participant visit date for Part A: 26 Mar 2021 The analyses presented in this report are based on a database lock date of 04 May 2021
Sponsor Medical Officer:	Allison August, MD
Date of Report:	05 August 2021

The study was conducted according to the International Council for Harmonisation harmonised tripartite guideline E6(R2): Good Clinical Practice.

CONFIDENTIAL

Synopsis 15
List of Abbreviations 43
1 Introduction 47
1.1 Background 47
1.2 Nonclinical Studies 48
1.3 Other Clinical Studies in the mRNA-1273 Development Plan 49
1.4 Study Rationale 52
2 Study Objectives and Endpoints 54
3 Investigational Plan 58
3.1 Overall Study Design and Plan 58
3.1.1 Part A, the Randomized, Placebo-Controlled, Blinded Phase 58
3.1.2 Part B, the Open-Label Observational Phase 60
3.1.3 Discussion of Study Design 62
3.2 Protocol Amendments and Other Changes in the Conduct of the Study 64
3.2.1 Changes in the Conduct of the Study 64
3.3 Investigators and Study Administrative Structure 66
3.4 Ethical Considerations 68
3.4.1 Independent Ethics Committee or Institutional Review Board 68
3.4.2 Ethical Conduct of the Study 68
3.4.3 Participant Information and Consent 68
3.5 Selection of Study Population 69
3.5.1 Inclusion Criteria 69
3.5.2 Exclusion Criteria 70
3.5.3 Withdrawal of Participants From the Study or Study Treatment 71
3.5.3.1 Participant Withdrawal From the Study 71
3.5.3.2 Participant Withdrawal From Study Treatment 73
3.6 Study Treatment 73
3.6.1 Investigational Product Administered 73

3.6.1.1 Contraindications to Subsequent Injection and Criteria for Delay of Study Treatment ... 73
3.6.2 Identity of Investigational Products ... 74
3.6.3 Method of Assigning Participants to Treatment Groups ... 76
3.6.4 Blinding and Unblinding ... 77
3.6.5 Treatment Compliance ... 79
3.6.6 Prior and Concomitant Medications and Therapies ... 79
3.6.6.1 Prior Medications and Therapies ... 79
3.6.6.2 Concomitant Medications and Therapies ... 79
3.7 Efficacy, Safety, and Immunogenicity Measurements Assessed and Schedule of Assessments ... 80
3.7.1 Study Assessments and Schedule of Events ... 80
3.7.1.1 Use of Electronic Diary ... 81
3.7.1.2 Safety Telephone Call ... 83
3.7.2 Efficacy Assessments ... 83
3.7.2.1 Surveillance for COVID-19 Symptoms ... 84
3.7.2.2 Assessments During Convalescence Period, Starting at Illness Visit ... 85
3.7.2.3 Testing for SARS-CoV-2 Infection ... 86
3.7.3 Immunogenicity Assessments ... 88
3.7.4 Safety Assessments ... 88
3.7.4.1 Solicited Adverse Reactions (Part A, Blinded Phase Only) ... 89
3.7.4.2 Adverse Events, Serious Adverse Events, and Medically Attended Adverse Events ... 90
3.7.4.3 Vital Sign Measurements ... 91
3.7.4.4 Physical Examinations ... 92
3.7.5 Other Assessments ... 92
3.7.5.1 Other Virus/Bacteria Infection Analysis ... 92
3.7.6 Appropriateness of Measurements ... 93
3.8 Data Quality Assurance ... 93
3.8.1 Data Collection and Management ... 94
3.8.2 Study Monitoring ... 95

3.8.5 Risk Management ... 98
3.8.6 Clinical COVID-19 Response ... 99

4 Statistical Analysis Methods Planned in the Protocol and Determination of Sample Size 101
4.1 Statistical Methods 101
4.1.1 General Considerations 101
4.1.1.1 Statistical Hypothesis 102
4.1.2 Determination of Sample Size 103
4.1.3 Analysis Sets 103
4.1.4 Handling of Withdrawals of Consent, Lost to Follow-Up, and Missing Data 105
4.1.5 Planned Analyses and Analyses of Efficacy Analyses That Have Been Conducted 106
4.1.5.1 Planned Interim Analyses and Primary Analysis 106
4.1.5.2 Analyses of Efficacy That Have Been Conducted 107
4.1.5.3 Final Analysis of Efficacy for Blinded Data (Part A) 108
4.1.6 Multiplicity Adjustments 109
4.1.7 Multicenter Studies 110
4.1.8 Adjustment for Covariates 110
4.1.9 Examination of Subgroups 110
4.2 Population, Efficacy, Safety, and Immunogenicity Statistical Analyses 110
4.2.1 Study Population 110
4.2.1.1 Disposition 110
4.2.1.2 Protocol Deviation 111
4.2.1.3 Demographics and Baseline Characteristics 111
4.2.1.4 Medical History 111
4.2.1.5 Prior, Concomitant, and Post Medications 112
4.2.1.6 Exposure 112
4.2.2 Efficacy Analyses 112
4.2.2.1 Analysis of the Primary Efficacy Endpoint 113
4.2.2.2 Analyses of the Secondary Efficacy Endpoints 119
4.2.2.3 Exploratory Efficacy Endpoint Analyses 122
4.2.3 Safety Analyses 125
4.2.3.1 Solicited Adverse Reactions 125
4.2.3.2 Unsolicited TEAEs 126
4.2.3.3 Vital Sign Measurements 128
4.2.3.4 Pregnancies 128
4.2.3.5 Vaccine-Associated Enhanced Respiratory Disease 128
4.2.4 Immunogenicity Analyses 128

4.2.4.1 Summary of Antibody-Mediated Immunogenicity Endpoints 129
4.2.4.2 Analysis of Antibody-Mediated Immunogenicity Endpoints 131
4.2.4.3 Summary of Immunogenicity in COVID-19 Cases on mRNA-1273 With Negative SARS-CoV-2 Status at Baseline 131
4.3 Changes to the Planned Analyses 132
5 Study Populations 133
5.1 Disposition of Participants 133
5.2 Study Analysis Sets 138
5.3 Predefined Quality Tolerance Limits Assessments 141
5.4 Major Protocol Deviations 141
5.5 Demographics and Other Baseline Characteristics 143
5.6 Medical History 155
5.7 Prior and Concomitant Medications 156
5.8 Exposure and Compliance 156
5.9 Duration of Follow-Up 156
6 Efficacy Results 160
6.1 Efficacy Results for Primary Endpoint 160
6.1.1 Interim Analysis (11 Nov 2020) and Primary Efficacy Analysis (25 Nov 2020) 160
6.1.2 Final Efficacy Analysis (04 May 2021) 162
6.1.2.1 Sensitivity Analysis Results for Final Blinded Efficacy 163
6.1.2.2 Subgroup Analysis Results for Final Blinded Efficacy 166
6.2 Efficacy Results for Secondary Endpoints 169
6.2.1 Severe COVID-19 169
6.2.2 SARS-CoV-2 Infection Regardless of Symptomatology and Severity 172
6.2.3 COVID-19 Starting 14 Days After the First Injection 175
6.2.4 Secondary Definition of COVID-19 176
6.2.5 Death Caused by COVID-19 178
6.2.6 Asymptomatic SARS-CoV-2 Infection 178
6.2.7 COVID-19 Regardless of Prior SARS-CoV-2 Infection 180
6.3 Efficacy Results for Exploratory Endpoints 183
6.3.1 Vaccine Efficacy to Reduce Duration and Presence/Severity of COVID-19 Symptoms 183
6.3.2 Vaccine Efficacy Against Burden of Disease 184
6.3.3 Vaccine Efficacy Against Burden of Infection 184

6.3.4 Efficacy Against Viral Load 184
6.3.5 All-Cause Mortality After Randomization 185
6.4 Genotypic Analysis of Variants 185
6.4.1 Efficacy Against Variants 185
6.5 Immunogenicity 186
6.5.1 SARS-CoV-2 Spike Protein-Specific Antibodies as Measured by Binding Antibody and Pseudovirus Neutralizing Antibody Assays 187
6.5.1.1 SARS-CoV-2 Spike Protein-Specific Binding Antibodies as Measured by MesoScale Discovery Assay 187
6.5.1.2 SARS-CoV-2 Spike Protein-Specific Binding Antibodies as Measured by ELISA 198
6.5.1.3 SARS-CoV-2 Spike Protein-Specific Neutralizing Antibodies as Measured by Pseudotyped Virus Neutralization Assay 209
6.5.2 Analysis of Breakthrough COVID-19 Cases 226
6.6 Drug Dose, Drug Concentration, and Relationships to Response 229
6.7 Drug-Drug and Drug-Disease Interaction 229
6.8 By-Participant Displays 229
6.9 Efficacy Conclusions 229
6.9.1 Primary Efficacy Conclusions 229
6.9.2 Secondary Efficacy Conclusions 229
6.9.3 Immunogenicity Conclusions 231
7 Safety Results 232
7.1 Solicited Adverse Reactions 232
7.1.1 Incidence and Severity of Solicited Adverse Reactions Starting Within 7 Days After Injection 232
7.1.2 Onset of Solicited Adverse Reactions 241
7.1.3 Duration (Number of Days) of Solicited Adverse Reactions 241
7.1.3.1 Solicited Adverse Reactions Persisting Beyond 7 Days After Injection 248
7.1.3.2 Local Adverse Reaction With Delayed Onset Beyond 7 Days After Injection 249
7.1.4 Solicited Adverse Reactions by Subgroup 251
7.1.4.1 Age Groups 251
7.1.4.2 Baseline SARS-CoV-2 Status 265
7.1.4.3 Race and Ethnicity 285
7.1.4.4 Sex 285
7.1.5 Medication Use for Solicited Adverse Reactions of Pain and Fever 286

7.2 Unsolicited Adverse Events 289
7.2.1 Overview of Unsolicited Adverse Events 289
7.2.1.1 Up to 28 Days After Injection 289
7.2.1.2 Overall Study Period in Part A 290
7.2.2 Unsolicited Adverse Events by Preferred Term 292
7.2.3 Unsolicited Adverse Events by Maximum Intensity 304
7.2.4 Unsolicited Adverse Events by Relationship to Investigational Product 304
7.2.5 Unsolicited Adverse Events Occurring Within 30 Minutes After Injection 319
7.2.6 Subgroup Analyses of Unsolicited Adverse Events 320
7.2.6.1 Age Groups 320
7.2.6.2 Baseline SARS-CoV-2 Status 324
7.2.6.3 Race and Ethnicity 327
7.2.6.4 Sex 327
7.2.6.5 Risk Factor for Severe COVID-19 327
7.2.6.6 Participants With Autoimmune Disorders 328
7.3 Deaths, Other Serious Adverse Events, and Other Significant Unsolicited Adverse Events 328
7.3.1 Deaths 328
7.3.2 Other Serious Adverse Events 331
7.3.3 Other Clinically Meaningful Unsolicited Adverse Events 357
7.3.3.1 Unsolicited Adverse Events Leading to Discontinuation From the Study Vaccine or From the Study 357
7.3.3.2 Medically Attended Treatment-Emergent Adverse Events 366
7.3.3.3 Analysis of Adverse Events of Clinical Interest 380
7.3.3.4 Vaccine-Associated Enhanced Respiratory Disease 382
7.3.4 Subgroup Analyses of Deaths, Other Serious Adverse Events, and Other Significant Unsolicited Adverse Events 382
7.3.4.1 Age Groups 382
7.3.4.2 Baseline SARS-CoV-2 Status 404
7.4 Clinical Laboratory Evaluation 404
7.5 Vital Signs and Other Observations Related to Safety 404
7.6 Pregnancies 404
7.7 Safety Conclusions 405

Synopsis

Title of Study: A Phase 3, Randomized, Stratified, Observer-Blind, Placebo-Controlled Study to Evaluate the Efficacy, Safety, and Immunogenicity of mRNA-1273 SARS-CoV-2 Vaccine in Adults Aged 18 Years and Older

Investigators: This was a multicenter study.

Study Centers: This study was conducted at 99 study sites in the United States.

Publication (Reference): Baden LR, El Sahly HM, Essink B, Kotloff K, Frey S, Novak R, et al. Efficacy and safety of the mRNA-1273 SARS-CoV-2 vaccine. N Eng J Med. 2021;384(5):403-16.

Study Period (Part A): 27 Jul 2020 (First participant first visit) to early unblinding, study discontinuation, the Part B participant decision visit (PDV) or data cutoff date (26 Mar 2021), whichever was earlier

Drug Development Phase: 3

Background and Rationale: An outbreak of coronavirus disease 2019 (COVID-19) caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) began in Wuhan, Hubei Province, China in December 2019 and the disease has since spread globally. On 11 Mar 2020, the World Health Organization declared COVID-19 a pandemic. Global efforts to evaluate novel antivirals and therapeutic strategies to treat severe SARS-CoV-2 infections have intensified, and there is an urgent public health need for rapid development of novel vaccines to prevent the spread of this disease. ModernaTX, Inc. (Sponsor) has used rapid response, proprietary, mRNA-based vaccine platform to develop a novel lipid nanoparticle (LNP)-encapsulated mRNA-based vaccine against SARS-CoV-2 (mRNA-1273).

Study mRNA-1273-P301 was designed as a Phase 3, randomized, stratified, observer-blind, placebo-controlled study to evaluate the efficacy, safety, and immunogenicity of mRNA-1273 SARS-CoV-2 vaccine compared to placebo in adults 18 years of age and older who have no known history of SARS-CoV-2 infection but whose occupation or location and living circumstances put them at increased risk of acquiring COVID-19 and/or SARS-CoV-2 infection. The primary goals of this Phase 3 study are to evaluate the vaccine efficacy (VE) of mRNA-1273 to prevent COVID-19, compared to placebo and to further evaluate the safety and reactogenicity profile of mRNA-1273.

This Part A clinical study report (CSR) presents the data from the randomized, placebo controlled, blinded phase (Part A) of the study based on the database lock on 04 May 2021, and includes available participant level data up to early unblinding, study discontinuation, the Part B PDV or data cutoff date (26 Mar 2021), whichever was earlier.

Objectives and Endpoints:

Objectives	Endpoints
Primary efficacy	

• To demonstrate the efficacy of mRNA-1273 to prevent COVID-19.	• The VE of mRNA-1273 to prevent the first occurrence of COVID-19 starting 14 days after the second dose of IP, where COVID-19 was defined as symptomatic disease based on the following criteria:
	  • The participant must have experienced at least TWO of the following systemic symptoms: fever (≥ 38ºC), chills, myalgia, headache, sore throat, new olfactory and taste disorder(s), OR
	  • The participant must have experienced at least ONE of the following respiratory signs/symptoms: cough, shortness of breath or difficulty breathing, OR clinical or radiographical evidence of pneumonia; AND
	  • The participant must have at least 1 NP swab, nasal swab, or saliva sample (or respiratory sample, if hospitalized) positive for SARS-CoV-2 by RT-PCR.

Primary safety	
• To evaluate the safety and reactogenicity of 2 injections of the mRNA-1273 vaccine given 28 days apart.	• Solicited local and systemic ARs through 7 days after each dose of IP. • Unsolicited AEs through 28 days after each dose of IP. • MAAEs or AEs leading to withdrawal through the entire study period. • SAEs throughout the entire study period. • Pregnancies and perinatal outcomes.

Objectives	Endpoints
Secondary efficacy	
• To evaluate the efficacy of mRNA-1273 to prevent severe COVID-19.	• The VE of mRNA-1273 to prevent severe COVID-19, defined as first occurrence of COVID-19 starting 14 days after the second injection of IP, (as per the primary endpoint) AND any of the following: • Clinical signs indicative of severe systemic illness, respiratory rate ≥ 30 per minute, heart rate ≥ 125 beats per minute, $SpO_2 \leq 93\%$ on room air at sea level, or PaO_2/FIO_2 < 300 mm Hg, OR • Respiratory failure or ARDS (defined as needing high-flow oxygen, non-invasive or mechanical ventilation, or ECMO), evidence of shock (systolic BP < 90 mm Hg, diastolic BP < 60 mm Hg, or requiring vasopressors), OR • Significant acute renal, hepatic, or neurologic dysfunction, OR • Admission to an intensive care unit or death.
• To evaluate the efficacy of mRNA-1273 to prevent serologically confirmed SARS-CoV-2 infection or COVID-19 regardless of symptomatology or severity.	• The VE of mRNA-1273 to prevent the first occurrence of either COVID-19 or SARS-CoV-2 infection starting 14 days after the second injection of IP. This endpoint includes COVID-19, as defined for the primary endpoint, and asymptomatic SARS-CoV-2 infection, determined by seroconversion assessed by bAb levels against SARS-CoV-2 as measured by a ligand-binding assay specific to the SARS-CoV-2 nucleocapsid protein or a positive RT-PCR test post baseline. This endpoint was evaluated in participants who were SARS-CoV-2 negative at baseline.
• To evaluate VE against a secondary definition of COVID-19.	• The VE of mRNA-1273 to prevent the secondary case definition of COVID-19 starting 14 days after the second injection of IP. The secondary case definition of COVID-19 was defined as the presence of at least 1 of the following systemic symptoms: fever (temperature ≥ 38ºC), or chills, cough, shortness of breath or difficulty breathing, fatigue, muscle aches or body aches, headache, new loss of taste or smell, sore throat, nasal congestion or rhinorrhea, nausea or vomiting, or diarrhea AND a positive NP swab, nasal swab, or saliva sample (or respiratory sample, if hospitalized) for SARS-CoV-2 by RT-PCR.
• To evaluate VE to prevent death caused by COVID-19.	• The VE of mRNA-1273 to prevent death due to a cause directly attributed to a complication of COVID-19, starting 14 days after the second injection of IP.

Objectives	Endpoints
• To evaluate the efficacy of mRNA-1273 to prevent COVID-19 after the first dose of IP.	• The VE of mRNA-1273 to prevent the first occurrence of COVID-19 starting 14 days after the first injection of IP.
• To evaluate the efficacy of mRNA-1273 to prevent COVID-19 in all study participants, regardless of evidence of prior SARS-CoV-2 infection.	• The VE of mRNA-1273 to prevent the first occurrence of COVID-19 starting 14 days after the second injection of IP regardless of evidence of prior SARS-CoV-2 infection (FAS analysis population).
• To evaluate the efficacy of mRNA-1273 to prevent asymptomatic SARS-CoV-2 infection.	• The VE to prevent the first occurrence of SARS-CoV-2 infection in the absence of symptoms defining COVID-19 starting 14 days after the second injection of IP. SARS-CoV-2 infection was determined by seroconversion assessed by bAb levels against SARS-CoV-2 as measured by a ligand-binding assay specific to the SARS-CoV-2 Nucleocapsid protein or a positive RT-PCR test at a scheduled visit (eg, predose on Day 29). This endpoint was evaluated in participants who were SARS-CoV-2 negative at baseline.
Secondary immunogenicity	
• To evaluate the immunogenicity of 2 doses of mRNA-1273 given 28 days apart.	• GMT of SARS-CoV-2 -specific nAb on Day 1, Day 29, Day 57, Day 209, Day 394, and Day 759[a]. • GMFR of SARS-CoV-2-specific nAb relative to Day 1 on Day 29, Day 57, Day 209, Day 394, and Day 759[a]. • Quantified levels or GMT of S protein-specific bAb on Day 1, Day 29, Day 57, Day 209, Day 394, and Day 759[a]. • GMFR of S protein-specific bAb relative to Day 1 on Day 29, Day 57, Day 209, Day 394, and Day 759[a].
Exploratory - The following exploratory objectives and endpoints are addressed in this CSR:	
• To evaluate the effect of mRNA-1273 on the viral infection kinetics as measured by viral load at SARS-CoV-2 infection diagnosis by RT-PCR and number of days from the estimated date of SARS-CoV-2 infection until undetectable SARS-CoV-2 infection by RT-PCR.	• The VE of mRNA-1273 on the viral infection kinetics as measured by viral load at SARS-CoV-2 infection diagnosis by RT-PCR and number of days from the estimated date of SARS-CoV-2 infection until undetectable SARS-CoV-2 infection by RT-PCR.
• To assess VE to reduce the duration of symptoms of COVID-19.	• The VE of mRNA-1273 to reduce duration of COVID-19 symptoms.
• To evaluate VE against all-cause mortality.	• The VE of mRNA-1273 against all-cause mortality.
• To assess VE against BOD due to COVID-19	• The VE of mRNA-1273 against BOD based on the post SARS-CoV-2 infection follow-up.
• To evaluate the genetic and/or phenotypic relationships of isolated SARS-CoV-2 strains to the vaccine sequence.	• The genetic and/or phenotypic relationships of isolated SARS-CoV-2 strains to the vaccine sequence.
• To conduct additional analyses related to furthering the understanding of SARS-CoV-2 infection and COVID-19, including analyses	• Additional analyses related to furthering the understanding of SARS-CoV-2 infection and

Objectives	Endpoints
related to the immunology of this or other vaccines, detection of viral infection, and clinical conduct.	COVID-19, including analyses related to the immunology of this or other vaccines, detection of viral infection, and clinical conduct.

Abbreviations: AE = adverse event; AR = adverse reaction; ARDS = acute respiratory distress syndrome; bAb = binding antibody; BOD = burden of disease; BP = blood pressure; CSR = clinical study report; ECMO = extracorporeal membrane oxygenation; FAS = Full Analysis Set; FIO_2 = fraction of inspired oxygen; GMFR = geometric mean fold rise; GMT = geometric mean titer; IP = investigational product; MAAE = medically-attended adverse event; nAb = neutralizing antibody; NP = nasopharyngeal; PaO_2 = partial pressure of oxygen; RT-PCR = reverse transcription polymerase chain reaction; SAE = serious adverse event; SpO_2 = oxygen saturation by pulse oximeter; VE = vaccine efficacy.

[a] This Part A CSR presents the immunogenicity endpoints through Day 57 for the Per-Protocol Random Subcohort for Immunogenicity.

Methodology:

This is an ongoing 2-part Phase 3 study: Part A and Part B. Participants in Part A, the randomized, placebo-controlled, blinded phase of this study, were blinded to their treatment assignment. Given that the primary efficacy endpoint for mRNA-1273 against COVID-19 was met per the protocol-defined interim analysis (IA), Part B, the Open-Label Observational Phase of this study, was designed to offer participants who received placebo in Part A of this study and who met Emergency Use Authorization (EUA) eligibility, an option to request open-label mRNA-1273 during a PDV.

This Part A CSR presents the data from the randomized, placebo-controlled, blinded phase (Part A) of the study based on the database lock on 04 May 2021, and includes available participant level data up to early unblinding, study discontinuation, the Part B PDV or data cutoff date (26 Mar 2021), whichever was earlier. Data from Part B, in which eligible participants were offered open-label mRNA-1273, will be included in a CSR addendum.

Part A, the Randomized, Placebo-Controlled, Blinded Phase

Part A of this study was a Phase 3, randomized, stratified, observer-blind, placebo-controlled study to evaluate the efficacy, safety, and immunogenicity of mRNA-1273 SARS-CoV-2 vaccine compared to placebo in adults 18 years of age and older who had no known history of SARS-CoV-2 infection but whose occupation or locations and living circumstances put them at appreciable risk of acquiring COVID-19 and/or SARS-CoV-2 infection.

Participants were randomly assigned to receive doses of either 100 µg of mRNA-1273 vaccine or placebo in a 1:1 randomization ratio. Assignment was stratified by age and health risk.

All participants were assessed for efficacy and safety endpoints. A nasopharyngeal (NP) swab sample and blood sample were obtained from each participant before the first and second dose of investigational product (IP). In addition, a series of postdose blood samples for immunogenicity

are being collected through 24 months after the second dose of IP. Efficacy assessments included surveillance for COVID-19 with reverse transcriptase polymerase chain reaction (RT-PCR) confirmation of SARS-CoV-2 infection after the first and second dose of IP.

Each participant received 2 doses of IP by 0.5 mL intramuscular (IM) injection, the first on Day 1 and the second on Day 29. An NP swab sample was collected prior to the first and second dose of IP for evaluation by RT-PCR. To preserve observer blinding, only delegated unblinded study site personnel responsible for IP preparation, administration, and/or accountability had knowledge of study IP assignment.

Participants were given an electronic diary (eDiary) to report solicited ARs for 7 days after each dose of IP and to prompt an unscheduled clinic visit for clinical evaluation and NP swab sample if a participant experienced any symptoms of COVID-19. Participants used the eDiary to report solicited ARs for the first 7 days after each dose of IP (or until resolution for solicited ARs that continued beyond 7 days) and were then followed by weekly eDiary prompts (every 7 days) to elicit an unscheduled Illness Visit if the participant experienced COVID-19 symptoms. All participants received safety calls on Day 8, Day 15, Day 22, Day 36, and Day 43 that served both to monitor for unsolicited adverse events (AEs) and to monitor for symptoms of COVID-19.

Safety telephone calls and eDiary safety prompts were performed in conjunction with surveillance for COVID-19 according to the SoEs and were intended to capture serious AEs (SAEs), medically attended AEs (MAAEs), AEs leading to withdrawal, concomitant medications associated with these events, receipt of non-study vaccinations, and pregnancy. If an eDiary prompt resulted in identification of a relevant safety event, a follow-up safety call was triggered.

Surveillance for signs and symptoms of COVID-19 is being performed through weekly contacts with the participant via a combination of telephone calls and completion of specific eDiary prompts starting at Day 1 through the end of the study. Participants with symptoms of COVID-19 lasting at least 48 hours (except for fever and/or respiratory symptoms) returned to the clinic or were visited at home by medically qualified study site personnel within 72 hours to collect an NP swab sample for RT-PCR testing for SARS-CoV-2 and other respiratory pathogens, or alternatively, if a clinic or home visit was not possible, submitted a saliva (or nasal swab) sample for SARS-CoV-2 RT-PCR testing.

All study participants who experienced COVID-19 symptoms and subsequently presented for an Illness Visit (in clinic or at home) were given an instruction card listing symptoms and severity grading system along with a thermometer, an oxygen saturation monitor, and saliva collection tubes. Study participants were contacted by the investigator (or appropriately delegated study site personnel) daily with telemedicine visits through Day 14 or until symptoms had resolved, whichever was later. During the telemedicine visit (preferably done in the evening), the

participant was asked to verbally report the severity of each symptom, their highest body temperature and lowest oxygen saturation for that day, and the investigator determined if medical attention was required due to worsening of COVID-19 symptoms. Study participants collected their own saliva (or nasal swab) sample at 3, 5, 7, 9, 14, and 21 days after the initial Illness Visit meeting criteria for COVID-19 (defined as the date of onset of symptoms and positive virologic test). Finally, a Convalescent Visit was scheduled approximately 28 days after the initial Illness Visit. At this visit, a saliva (or nasal swab) sample was collected and a blood sample was drawn for immunologic assessment of SARS-CoV-2 infection.

At each IP injection visit, participants were instructed (Day 1) or reminded (Day 29) on how to document and report solicited ARs in the eDiary provided. Solicited ARs were assessed for 7 days after each IP injection (or until resolution for solicited ARs that continued beyond 7 days), and unsolicited AEs were assessed for 28 days after each injection; SAEs, MAAEs, and AEs leading to withdrawal were assessed throughout the study.

Participants may have experienced AEs that necessitated an unscheduled visit. There may have also been situations in which the investigator asked a participant to report for an unscheduled visit following the report of an AE. Additional examinations may have been conducted at these visits as necessary to ensure the safety and well-being of participants during the study. Electronic case report forms (eCRFs) should have been completed for each unscheduled visit.

Number of Participants (Planned and Analyzed): Approximately 30,000 participants were planned to receive doses of either 100 μg of mRNA-1273 vaccine or placebo in a 1:1 randomization ratio.

In Part A, a total of 30,415 participants were randomized (Randomized Set): 15,206 in the placebo group and 15,209 in the mRNA-1273 group. Of these, 22,882 participants were ≥ 18 and < 65 years and 7,533 participants were ≥ 65 years. The number of participants included in the analysis sets used for the primary analyses of efficacy, immunogenicity, and safety are summarized as follows:

- Per-Protocol Set: 28,451 (93.5%) total (14,164 [93.1%] in the placebo group and 14,287 [93.9%] in the mRNA-1273 group)
- Per-Protocol Random Subcohort for Immunogenicity: 1,457 (4.8%) total (272 [1.8%] in the placebo group and 1,185 [7.8%] in the mRNA-1273 group)
- Safety Set: 30,346 total (15,162 in the placebo group and 15,184 in the mRNA-1273 group)

Main Criteria for Inclusion and Exclusion: Participants (males and females 18 years of age or older at time of consent), who were at high risk of SARS-CoV-2 infection, defined as adults

whose locations or circumstances put them at appreciable risk of exposure to the virus, who were heathy and had no known history of SARS-CoV-2 infection, or adults with pre-existing medical conditions who were in stable condition at screening comprised the planned target population. Additionally, potential study participants at high risk of severe COVID-19 were included based on age (65 years of age and older) and underlying medical conditions.

Test Product, Dose and Mode of Administration: mRNA-1273 was administered as an 0.5 mL IM injection containing 100 µg of mRNA-1273 into the deltoid muscle (preferably the nondominant arm) on a 2-dose injection schedule on Day 1 and Day 29 in Part A. The second dose of IP should have been administered in the same arm as the first dose.

Control Product, Dose and Mode of Administration: Placebo (0.9% sodium chloride) was administered as an 0.5 mL IM injection into the deltoid muscle on an identical schedule as mRNA-1273.

Duration of Treatment: Participants received the randomly assigned IP of mRNA-1273 or placebo as 2 injections administered 28 days apart (Day 1 and Day 29) in Part A.

Estimands and Intercurrent Events: The estimand of the primary analysis was VE measured using 1 – HR (mRNA-1273 vs. placebo) for prevention of first occurrence of COVID-19 from 14 days after second dose of IP in adults.

Statistical Methods:

Analysis Sets: The following analysis sets were defined:

- **Randomized Set:** All participants who were randomized, regardless of the participant's treatment status in the study. Participants were analyzed according to the treatment group to which they were randomized.
- **Full Analysis Set (FAS):** All randomized participants who received at least 1 dose of IP. Participants were analyzed according to the treatment group to which they were randomized.
- **Modified Intent-to-Treat (mITT) Set:** All participants in the FAS who had no immunologic or virologic evidence of prior COVID-19 (negative SARS-CoV-2 status, ie, negative NP swab test and negative bAb against SARS-CoV-2 N-protein as measured by Roche Elecsys®) at Day 1 before the first dose of IP; ie, all FAS participants excluding those with RT-PCR and/or serology positive at baseline (Day 1 before the first dose of IP). Participants were analyzed according to the treatment group to which they were randomized.

- **PP Set:** All participants in the mITT Set who received planned doses of IP per schedule and had no major protocol deviations, as determined and documented by the Sponsor prior to database lock and unblinding, which impacted critical or key study data. Participants were analyzed according to the treatment group to which they were randomized. Participants who did not receive the second injection of IP within [21, 42] days after the first injection date were excluded from the PP Set.
- **Immunogenicity Subset and Analysis Populations for Immunogenicity:** For characterizing immunogenicity of the vaccine and for assessing correlates of risk and protection, a case-cohort sampling design was used for measuring bAb and nAb data from a randomly sampled subset of study participants (the case-cohort Immunogenicity Analysis Set [ccIAS]) or immunogenicity subset. The ccIAS cohort consisted of a stratified, random sample of study participants (random subcohort) augmented with a subset or all primary endpoint cases and SARS-CoV-2 infection endpoint cases. The immunogenicity samples of the ccIAS cohort were processed and the immunogenicity data were available for the ccIAS cohort. The immunogenicity subset consisted of all participants in the ccIAS who had a valid baseline immunogenicity test result (prior to the first dose of IP) and at least 1 valid post-baseline result.
- The **Per-Protocol Random Subcohort for Immunogenicity** (PPRSI) was used as the analysis population to characterize immunogenicity of mRNA-1273. The PPRSI for immunogenicity consisted of participants in the FAS who were sampled into the random subcohort and
    a) Received both planned doses (ie, received the treatment as the participant was randomized to) with Dose 2 received within [21, 42] days after Dose 1, and
    b) No major protocol deviation that impacted critical or key data.
- **Solicited Safety Set:** All randomized participants who received at least 1 dose of IP and contributed any solicited AR data; ie, had at least 1 post-baseline solicited safety (eDiary) assessment. The Solicited Safety Set was used for the analyses of solicited ARs, and participants were included in the treatment group corresponding to the study vaccination they actually received.

  In addition, the following Solicited Safety Set was defined for each injection separately. **The First (Second) Injection Solicited Safety Set** consisted of all participants in the Solicited Safety Set who received the first (second) study injection and contributed any solicited AR data (eDiary) from the time of first (second) study injection through the following 6 days.

Participants were analyzed according to the treatment group a participant received, rather than the treatment group to which the participant was randomized. If a participant was randomized to placebo but received any dose of mRNA-1273 vaccine at any injection, the participants were included in the mRNA-1273 group in the Solicited Safety Set.

- **Safety Set:** All randomized participants who received at least 1 dose of IP. The Safety Set was used for all analysis of safety except for the solicited ARs. Participants were included in the treatment group corresponding to the IP they actually received. For a participant who was randomized to placebo but received any dose of mRNA-1273 at any injection, the participant will be included in the mRNA-1273 group in the Safety Set.

Efficacy: The PP Set was the primary analysis population for efficacy analyses, unless otherwise specified.

Primary Efficacy Endpoint:

The number and percentage of participants who had an event (ie, the first occurrence of COVID-19 starting 14 days after the second injection) and the participants who were censored were summarized.

The non-parametric Kaplan-Meier method was used to estimate the time to first occurrence of COVID-19 curve in each treatment group.

Vaccine efficacy was defined as the percent reduction in the hazard of the primary endpoint (mRNA-1273 vs. placebo), ie, 1 – HR. The null hypothesis was:

$$H_0^{efficacy}: VE \leq 0.3$$

Equivalently, the null hypothesis was:

$$H_0^{efficacy}: HR \geq 0.7$$

A stratified Cox proportional hazard model with Efron's method of tie handling and with treatment group as covariate was used to assess the magnitude of the treatment group difference (ie, HR) between mRNA-1273 and placebo. The same stratification factors used for randomization were applied to the stratified Cox model. The VE with corresponding alpha adjusted confidence interval (CI), 95% CI, and 1-sided *p* value for testing the null hypothesis from the stratified Cox model was reported at a planned IA up to the analysis at which VE was demonstrated. After VE was demonstrated, VE and 95% CI were to be provided for subsequent analysis/updates of efficacy.

In this study, VE was demonstrated based on prespecified statistical criterion at the IA, at which, 1-sided *p* value for testing the null hypothesis of VE ≤ 0.3, 95% CI, and alpha-adjusted CI were provided from the stratified Cox model. At the primary analysis where the total number of

COVID-19 cases > 151, total target number of cases, VE, 1-sided *p* value for testing the null hypothesis of VE ≤ 0.3, and 95% CI were provided. In subsequent analysis/updates of efficacy, VE and 95% CI were provided.

The number and percentage of participants who had an event (ie, the first occurrence of COVID-19 at least 14 days after the second injection) were reported.

Sensitivity analyses were performed, with COVID-19 cases counted starting at various time points using the PP Set as follows:

- After the second injection of IP
- Fourteen days after the first injection of IP (also as primary analysis approach for the secondary efficacy objective: to evaluate the efficacy of mRNA-1273 to prevent COVID-19 after the first dose of IP).
- After randomization

Analysis of the primary efficacy endpoint based on the mITT Set was also performed using the same statistical methods used for the primary analysis. The sensitivity analyses, with COVID-19 cases counted starting at various time points were also performed using the mITT Set.

To assess consistency of VE across various subgroups, subgroup analyses of the primary efficacy endpoint were performed based on the PP Set. The primary efficacy endpoint was analyzed by each of the subgroups using the same methods described for the primary analysis (ie, stratified Cox proportional hazard model with Efron's method of tie handling with a single treatment covariate), and the estimate of VE and its 95% CI were provided within each category of the following subgroups:

- Age groups: ≥ 18 and < 65 years, ≥ 65 years
- Age groups: ≥ 18 and < 65 years, ≥ 65 years and < 75 years, ≥ 75 years
- Stratification factor at randomization: ≥ 18 and < 65 years and not at risk, ≥ 18 and < 65 years at risk, ≥ 65 years
- Sex (female, male)
- Race
- Ethnicity
- Race and ethnicity: non-Hispanic White, communities of color
- Each risk factor for severe COVID-19 illness

Secondary Efficacy Endpoints:

Similar analysis methods, as detailed for the primary efficacy endpoint, were applied to the following secondary efficacy endpoints based on the PP Set, unless otherwise specified:

- VE to prevent severe COVID-19.
- VE to prevent serologically confirmed SARS-CoV-2 infection or COVID-19 regardless of symptomatology or severity.

  The analysis population for this endpoint, serologically confirmed SARS-CoV-2 infection or COVID-19 regardless of symptomatology or severity [COV-INF], was the PP Set (primary analysis population) and the mITT Set that included participants with negative SARS-CoV-2 status at baseline. Infection [COV-INF] was defined by any post-baseline positive RT-PCR results, and/or, seroconversion due to infection defined as positive bAb specific to SARS-CoV-2 NP as measured by Roche Elecsys at post-baseline scheduled visits for participants with negative SARS-CoV-2 status at baseline (PP and mITT Sets). Both RT-PCR tests from the scheduled NP swab tests at Day 29 as well as those prompted by symptom(s) were considered. A COVID-19 case or secondary definition of COVID-19 case was always a COV-INF case.
- VE to prevent COVID-19 using a secondary definition of symptoms.
- VE to prevent death caused by COVID-19

For each of the above secondary endpoints, the following analyses were performed:

- VE was estimated with 1 – HR (mRNA-1273 vs. placebo) using a Cox proportional hazard model based on the PP Set as described for the primary efficacy endpoint. Kaplan-Meier curves of time to event were presented for each treatment group. Cases were counted starting 14 days after the second injection of IP.
- Analysis was performed using the same model based on the mITT Set as described for the primary efficacy endpoint. Kaplan-Meier curves of time to event were presented for each treatment group.
- Sensitivity analyses were performed, with cases counted starting immediately after the second injection of IP (onset date ≥ date of second injection, considering positive RT-PCR at Day 29), starting 14 days (≥ 14 days) after the first injection of IP, and immediately after randomization, respectively.
- VE and 95% CI based on the incidence were estimated with 1 – ratio of incidence rates using the exact method conditional upon the total number of cases.

For the secondary efficacy objective: VE to prevent asymptomatic SARS-CoV-2 infection

- The analysis populations for asymptomatic infection were the PP Set (primary analysis population) and mITT Set. Asymptomatic infection was COV-INF (detected by positive RT-PCR or seroconversion [bAb specific to SARS-CoV-2 NP as measured by Roche Elecsys at scheduled visits]) with absence of symptoms.

  As diseased cases (COVID-19 or secondary definition of COVID-19) were competing events for asymptomatic SARS-CoV-2 infections, competing risk method (Fine and Gray's [FG] subdistribution hazard model) was used to estimate the VE of mRNA-1273. Competing risk method was also used to estimate the cumulative incidence function, and the cumulative incidence of asymptomatic SARS-CoV-2 infections were plotted.

  In the primary approach with cases of asymptomatic SARS-CoV-2 infection counted starting 14 days after the second injection, only seroconversion at Day 57 or later was to be considered.

  As serum samples were taken at scheduled visits (eg, Day 29 [Month 1], Day 57 [Month 2]), sensitivity analyses with cases counted starting after second injection, 14 days after the first injection, after the first injection, and after randomization were the same. Only 1 set of sensitivity analysis with cases counted starting from randomization was provided. In this sensitivity analysis, asymptomatic cases detected by positive RT-PCR result at scheduled Day 29 (before the second injection), or seroconversion at time points with scheduled visits were considered. Sensitivity analysis using the mITT Set with cases counted starting from 14 days after the second injection, and from randomization were also performed.

For the secondary efficacy objective: VE to prevent COVID-19 after the first injection of IP

- This endpoint was analyzed as a sensitivity analysis of the primary efficacy endpoint with cases counted starting 14 days (≥ 14 days) after the first injection of IP.

For the secondary efficacy objective: VE to prevent COVID-19 disease regardless of prior SARS-CoV-2 infection

- VE to prevent COVID-19 disease regardless of prior SARS-CoV-2 infection was analyzed using the FAS. The same methods described for the primary efficacy endpoint were applied with cases counted starting 14 days after the second injection of IP.

Sensitivity analyses with cases counted starting immediately after the second injection, 14 days after the first injection, and after randomization were also performed. In sensitivity analysis with cases counted starting after the second injection, participants who received only the first injection and were cases, were censored at the time of COVID-19.

The VE was also estimated with 1 – the ratio of incidence rates with the 95% CI using the exact method conditional upon the total number of cases adjusting for person-time.

In addition, an exploratory analysis with the same Cox model was performed in the subgroup of the FAS whose baseline SARS-CoV-2 status was positive with cases counted starting 14 days after the second dose to assess the VE in those with positive baseline SARS-CoV-2 status, at baseline, if sample size permitted. Such analysis in the subgroup of the FAS whose baseline SARS-CoV-2 status was negative with cases counted starting 14 days after the second dose was the same as the sensitivity analysis of COVID-19 starting 14 days after the second dose in the mITT Set.

Immunogenicity: The PPRSI was used as the analysis population to characterize immunogenicity of mRNA-1273.

Data from quantitative immunogenicity assays were summarized for each treatment group using positive response rates and geometric means (GMs) with 95% CI at each time point when an assessment was performed. Data from qualitative (ie, yielding a positive or negative result) assays were summarized by tabulating the frequency of positive responses for each assay by treatment group and by baseline SARS-CoV-2 status, if applicable, at each time point that an assessment was performed.

At the time the final blinded efficacy analysis, immunogenicity analyses to characterize immunogenicity of mRNA-1273 were performed. At the time of the immunogenicity analyses, data for bAb to S (MSD, PPD-VAC65) and psVNA ID_{50} and ID_{80} titers were available. The assay by MSD to measure bAb against RBD and N-protein had not yet been validated at the time of the immunogenicity analysis; therefore, these data were not summarized/analyzed. Immunogenicity data at the prespecified time points (Baseline [Day 1], Day 29 [Month 1], and Day 57 [Month 2]) were included.

- The GMT or value with corresponding 95% CI was provided at each time point. The 95% CIs were calculated based on the *t*-distribution of the log-transformed values then back transformed to the original scale for presentation. The following descriptive statistics were also provided at each time point: the number of participants (n), median, minimum, and maximum.

- The geometric mean fold rise (GMFR) with corresponding 95% CI was provided at each post-baseline time point over pre-injection baseline at Day 1. The 95% CIs were calculated based on the *t*-distribution of the log-transformed values then back transformed to the original scale for presentation. The following descriptive statistics were also provided at each time point: the number of participants (n), median, minimum, and maximum.
- Reverse cumulative distribution function curve (RCDF) at each time point. The number and percentage of participants with fold-rise ≥ 2, fold-rise ≥ 3, and fold-rise ≥ 4 from baseline at each post-injection time point were tabulated with 2-sided 95% Clopper-Pearson CIs.
- The Ab assay of interest [bAb to spike (MSD, PPD-VAC65) and PsVNA ID_{50} and ID_{80}] are listed in the table below. For each of them, seroresponse rate was defined as the proportion of participants achieving seroresponse, defined below for each assay/test of interest. Please note that these assay-specific definition of seroresponse was an update of 'seroconversion due to vaccination' used in the protocol and relevant SAP incorporating assay-specific fold-rise criteria based on assay-specific performance characteristics. These assay-specific definitions of seroresponse were documented in a memo that became available prior to DBL.

Assay Name	Category	Test Name/ Description	Definition of Seroresponse
Pseudovirus (PsVNA)	nAb	PsVNT50 (ID_{50})	baseline <LLOQ: ≥LLOQ baseline ≥LLOQ: 3.3-fold rise
		PsVNT80 (ID_{80})	baseline <LLOQ: ≥LLOQ baseline ≥LLOQ: 2.3-fold rise
Anti-Spike ELISA	bAb	anti-Spike VAC65 Spike IgG Antibody	baseline <LLOQ: ≥LLOQ baseline ≥LLOQ: 4.6-fold rise
MSD multiplex	bAb	anti-Spike	baseline <LLOQ: ≥LLOQ baseline ≥LLOQ: 1.9-fold rise

Abbreviations: bAb = binding antibody; ELISA = enzyme-linked immunosorbent assay; IgG = immunoglobulin G; LLOQ = lower limit of quantitation; MSD = MesoScale Discovery; nAb = neutralizing antibodies; PsVNA = pseudotyped virus neutralization assay; PsVNT50 = 50% pseudotyped lentivirus reporter test; PsVNT80 = 80% pseudotyped lentivirus reporter test.

- Number and proportion of participants achieving seroresponse were provided with 2-sided 95% Clopper-Pearson CIs at each post-baseline time point.

To assess the magnitudes of the differences between the 2 treatment groups (mRNA-1273 vs. placebo) in SARS-CoV-2-specific nAb and S protein-specific bAb, a mixed-effect model repeated measures (MMRM) using SAS PROC MIXED was used. The geometric least squares mean (GLSM) and corresponding 2-sided 95% CI for the antibody titers for each treatment

group were provided by visit. The GLSM and corresponding 95% CI results in log-transformed scale estimated from the model were back-transformed to obtain these estimates in the original scale. Geometric mean ratio (GMR), estimated by the ratio of GLSM and the corresponding 2-sided 95% CI, was provided to assess the treatment difference between the mRNA-1273 versus placebo groups at each visit. With each treatment group, within-group comparison of time points may also have been estimated using the same model.

In addition, an analysis of covariance (ANCOVA) model with the treatment group as explanatory variables, adjusting for the stratification factor at randomization, baseline value if applicable, was used to assess the treatment effect at specific time points (scheduled visits) such as Day 57. The GLSM with 95% CI for each treatment group, GMR with 95% CI for treatment difference was estimated from the ANCOVA model. The model also adjusted for minority group used to sample for the random subcohort.

It was of interest to examine the immune response in participants on mRNA-1273 with baseline SARS-CoV-2 negative status who were COVID-19 or SARS-CoV-2 infection cases. Immunogenicity data was provided in a subset of baseline SARS-CoV-2 negative participants on mRNA-1273 who were adjudicated COVID-19 cases.

Safety: Safety and reactogenicity were assessed by clinical review of all relevant parameters including solicited ARs (local and systemic), unsolicited AEs, SAEs, MAAEs, AEs leading to withdrawal from study vaccine and/or study participation, vital signs, and physical examination findings.

All safety analyses were based on the Safety Set, except summaries of solicited ARs which were based on the Solicited Safety Set. All safety analyses were provided by treatment group, unless otherwise specified.

Solicited ARs:

The number and percentage of participants who reported each individual solicited local AR and solicited systemic AR during the 7-day follow-up period (or until resolution for solicited ARs that continued beyond 7 days) after each injection were provided by severity grade. The number and percentage of participants who reported each individual solicited AR were also summarized by severity grade, days of reporting, and injection.

The number and percentage of participants experiencing fever (a temperature greater than or equal to 38.0°C/100.4°F by the oral, axillary, or tympanic route) by severity grade and the number and percentage of participants experiencing a fever of Grade 3 or higher temperature (a temperature greater than or equal to 39.0°C/102.1°F by the oral, axillary, or tympanic route) were summarized.

A 2-sided 95% exact CI using the Clopper-Pearson method was provided for the percentage of participants who reported any solicited local AR, solicited systemic AR, or any solicited AR.

The number and percentage of participants with onset of individual solicited AR were summarized by study day relative to the corresponding injection (Day 1 through Day 7). All solicited ARs that continued beyond 7 days post injection were summarized.

The above analyses of solicited ARs were summarized separately for the following subgroups:

- Age group (< 65 and ≥ 65 years)
- Sex (male, female)
- Baseline SARS-CoV-2 status
- Race and ethnicity

Unsolicited AEs:

Unsolicited TEAE summaries were provided for TEAEs up to 28 days after any injection and during Part A.

The overall summaries of unsolicited TEAEs (number and percentage) by treatment group included the following: any unsolicited TEAEs, any serious TEAEs, any unsolicited TEAEs that were MAAEs, any unsolicited TEAEs leading to discontinuation from participation in the study or study vaccine, any unsolicited severe TEAEs (severity of AEs was assessed as mild, moderate, or severe), and any unsolicited fatal TEAEs. The overviews also included a summary of participants with treatment-related TEAEs in each category.

The following summary tables of TEAEs were provided by SOC and preferred term (PT) using frequency counts and percentages (ie, number and percentage of participants with an event):

- All unsolicited TEAEs
- All treatment-related unsolicited TEAEs
- All SAEs
- All treatment-related SAEs
- All unsolicited TEAEs leading to discontinuation from study vaccine
- All unsolicited TEAEs leading to discontinuation from participation in the study
- All unsolicited severe TEAEs
- All treatment-related unsolicited severe TEAEs

- All unsolicited TEAEs that were MAAEs

A summary of TEAEs by maximum toxicity grade (mild, moderate, and severe) using frequency counts and percentages was provided for all unsolicited TEAEs and all treatment-related unsolicited TEAEs.

The overview of TEAEs and the TEAE summaries presented by SOC and PT were also summarized for the following subgroups: age (< 65 and ≥ 65 years), sex (male, female), and baseline SARS-CoV-2 status.

Separate listings of individual participant AE data were provided for the following: unsolicited TEAEs leading to discontinuation from study vaccine, unsolicited TEAEs leading to discontinuation from participation in the study, SAEs, treatment-related SAEs, and unsolicited treatment-related MAAEs. A listing of deaths including cause of death and a listing of TEAEs in participants who died were provided.

Other Safety:

Observed values and changes from baseline for all vital sign measurements were summarized at each visit by baseline SARS-CoV-2 serostatus and treatment group. Shift from baseline in the toxicity grades at each visit were summarized by treatment group.

Pregnancies and outcome (if available) were summarized by treatment group and a listing of pregnancies including outcome were provided.

Summary of Results:

Participant Disposition: A total of 30,415 participants were randomly assigned to study treatment: 15,206 participants in the placebo group and 15,209 in the mRNA-1273 group. Of these, 99.8% of participants overall received the first injection and 96.5% received the second injection.

A total of 531 participants (3.5%) who were randomly assigned to receive placebo and 453 participants (3.0%) who were randomly assigned to receive mRNA-1273 discontinued the study vaccine. The most common reasons for discontinuation of study vaccine were confirmed SARS-CoV-2 infection (ie, diagnosed COVID-19 by detection of SARS-CoV-2 in Day 1 NP swab or COVID-19 diagnosed prior to Day 29), other, and withdrawal of consent by participant.

A total of 2099 participants (13.8%) who were randomly assigned to receive placebo and 730 participants (4.8%) who were randomly assigned to receive mRNA-1273 discontinued the study, Part A and Part B inclusive. The imbalance of discontinuations between the placebo and mRNA-1273 groups coincided with the EUA of the Pfizer BioNTech COVID-19 vaccine and the Moderna COVID-19 vaccine.

IP Exposure in Part A: A total of 30,346 participants received the first injection: 15,162 received placebo and 15,184 received mRNA-1273. Of these, 29,362 participants (96.8%) received the second injection: 14,631 (96.5%) received placebo and 14,731 (97.0%) received mRNA-1273.

A total of 13 participants (7 participants in the placebo group; 6 participants in the mRNA-1273 group) received incorrect study vaccination per the randomization schedule.

Duration of Follow-up: Overall, the median duration of follow-up after randomization for the entire period up to the data cutoff for DBL (26 Mar 2021; inclusive of Part A and Part B) was 212 days (range, 1 to 243 days): 211 days in participants ≥ 18 to < 65 years and 214 days in participants ≥ 65 years.

The median duration of follow-up from randomization to PDV (ie, Part A) for participants who had a PDV on or before the data cutoff date was 148 days (range, 30 to 241 days): 148 days (range, 31 to 241 days) in participants ≥ 18 to < 65 years and 147 days (range, 30 to 234 days) in participants ≥ 65 years.

Demography and Baseline Characteristics: Overall, in the FAS, participant demographics and baseline characteristics were similar between the groups. A slightly higher proportion of males versus females (52.6% versus 47.4%. respectively) were enrolled. The mean age at screening was 51.4 years (range: 18 to 95 years); 75.2% of participants were ≥ 18 to < 65 years of age and 24.8% were ≥ 65 years. The majority of participants were White (79.2%) and not Hispanic or Latino (78.6%). Communities of color comprised 37.2% of the study population; the racial and ethnicity proportions observed in this study were generally representative of US demographics.

The study enrolled a total of 41.5% of participants who were considered at risk for severe COVID-19 (16.7% participants who were < 65 years and at risk, and 24.8% participants who were ≥ 65 years).

Overall, the majority of participants (82.5%) had a specified occupational risk for acquisition of SARS-CoV-2 infection; the most common occupational risks included other (31.9%) and health care workers (25.2%). A total of 83.8% of participants had a location or living circumstances risk for acquisition of SARS-CoV-2.

Efficacy Results: The results of the primary and secondary efficacy endpoint analysis are summarized for the PP Set in Table S-1 and presented graphically in Figure S-1.

Table S-1: Summary of Primary and Secondary Efficacy Endpoint Analysis Results (Per-Protocol Set)

	Placebo (N=14164)	mRNA-1273 (N=14287)
COVID-19* based on adjudication committee assessments starting 14 days after second injection		
Number of events	744	55
Vaccine efficacy based on hazard ratio (95% CI) [a]		0.932 (0.910, 0.948)
p-value [b]		<.0001
COVID-19* starting 14 days after second injection		
Number of events	751	55
Vaccine efficacy based on hazard ratio (95% CI) [a]		0.932 (0.911, 0.949)
Severe COVID-19* based on adjudication committee assessments starting 14 days after second injection		
Number of events	106	2
Vaccine efficacy based on hazard ratio (95% CI) [a]		0.982 (0.928, 0.996)
Severe COVID-19* starting 14 days after second injection		
Number of events	118	3
Vaccine efficacy based on hazard ratio (95% CI) [a]		0.976 (0.924, 0.992)
SARS-CoV-2 infection regardless of symptomatology and severity starting 14 days after second injection [c]		
Number of events	1339	280
Vaccine efficacy based on hazard ratio (95% CI) [a]		0.820 (0.795, 0.842)
Secondary definition of COVID-19* starting 14 days after second injection		
Number of events	807	58
Vaccine efficacy based on hazard ratio (95% CI) [a]		0.934 (0.914, 0.949)
Death caused by COVID-19 starting 14 days after second injection		
Number of events	3	0
Vaccine efficacy based on hazard ratio (95% CI) [a]		1.000 (NE, 1.000)
COVID-19* based on adjudication committee assessments starting 14 days after first injection		
Number of events	769	56
Vaccine efficacy based on hazard ratio (95% CI) [a]		0.933 (0.911, 0.949)

	Placebo (N=14164)	mRNA-1273 (N=14287)
COVID-19* starting 14 days after first injection		
Number of events	782	58
Vaccine efficacy based on hazard ratio (95% CI) [a]		0.931 (0.910, 0.947)
Asymptomatic SARS-CoV-2 infection starting 14 days after second injection [c]		
Number of events	498	214
Vaccine efficacy based on hazard ratio (95% CI) [a]		0.630 (0.566, 0.685)
COVID-19* based on adjudication committee assessments starting 14 days after second injection regardless of prior SARS-CoV-2 infection, n/N [d]		
Number of events	754/15166	58/15180
Vaccine efficacy based on hazard ratio (95% CI) [a]		0.928 (0.906, 0.945)
COVID-19* starting 14 days after second injection regardless of prior SARS-CoV-2 infection, n/N [d]		
Number of events	762/15166	58/15180
Vaccine efficacy based on hazard ratio (95% CI) [a]		0.929 (0.907, 0.946)

Abbreviations: CI = confidence interval; RT-PCR = reverse transcription polymerase chain reaction.

* With the censoring rules for efficacy analyses. COVID-19 case is based on eligible symptoms and positive RT-PCR within 14 days. If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys.

[a] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor. For asymptomatic SARS-CoV-2 infection, VE and 95% CI are estimated using Fine and Gray's sub-distribution hazard model with disease cases as competing events and with the treatment group as a covariate, adjusting for stratification factor.

[b] 1-sided p-value from stratified Cox proportional hazard model to test the null hypothesis VE <= 0.3.

[c] Including participant decision visit.

[d] n and N are based on the number of subjects in the Full Analysis Set.

Source: Figure 14.2.1.1.1.2.

The primary efficacy endpoint was VE of mRNA-1273 to prevent the first occurrence of adjudicated COVID-19 starting 14 days after the second dose of IP in the PP Set.

The final efficacy analysis of the primary endpoint for Part A (04 May 2021) was performed on 799 cases. The results of this analysis were consistent with the results of the interim and primary efficacy analyses, confirming persistent, high efficacy over a substantially larger case database over a longer median observation period of over 5.3 months. For the final efficacy analysis, the VE point estimate was 93.2% ($p < 0.0001$) and within the 95% CIs of the VE point estimates for the interim and primary efficacy analyses.

- Divergence of case incidence began early between mRNA-1273 and placebo groups, starting in the period from randomization up to 14 days after the first injection. Thereafter, cumulative incidence rate for the placebo group increased steadily while it remained stable and low in the mRNA-1273 group for the remainder of the observation period.
- Vaccine efficacy was consistent across subgroups for the primary efficacy endpoint.

The VE of mRNA-1273 to prevent adjudicated severe COVID-19 cases starting 14 days after second injection was consistent with the VE for the primary endpoint and was numerically higher than the VE for the primary endpoint.

- For the final analysis of efficacy for Part A, 108 participants had adjudicated severe COVID-19 starting 14 days after second injection in the PP Set (106 cases in the placebo group and 2 cases in the mRNA-1273 group); the VE point estimate based on the hazard ratio was 98.2%, confirming and extending the primary analysis of 25 Nov 2020 based on more than 3 times as many cases accrued over an approximately 2 times longer period of observation.
- Divergence of case incidence of severe COVID-19 began early between mRNA-1273 and placebo groups, starting in the period from 7 to 14 days after the first injection.
- Subgroup analyses were consistent with the primary analysis of efficacy and the point estimates of efficacy remained very high. Consistent VE point estimates were observed in subgroup analyses of participants with 1 risk factor, at last 2 risk factors, chronic lung disease, significant cardiac disease, severe obesity, diabetes, liver disease, and human immunodeficiency virus (HIV) infection.

The VE of mRNA-1273 to prevent SARS-CoV-2 infection, regardless of COVID-19 symptomatology and severity starting 14 days after second injection was consistent with the VE for the primary endpoint.

- Including the RT-PCR and Elecsys results from the PDV, a total of 1,619 participants had a SARS-CoV-2 infection starting 14 days after second injection in the PP Set (1,339 cases in the placebo group and 280 cases in the mRNA-1273 group); the VE point estimate based on the hazard ratio was 82.0%.
- Compared to the primary endpoint analyses, there were similar early onset of divergence in case incidence between treatment groups and similar stable and low rate of incidence rate for mRNA-1273 with increasing incidence rate in the placebo group.
- There were consistent, high VE point estimates across subgroups.

For the less restrictive secondary definition of COVID-19, the VE of mRNA-1273 was consistent with the VE for the primary endpoint, indicating that mRNA-1273 is efficacious even against mild COVID-19.

The VE to prevent asymptomatic SARS-CoV-2 infection was analyzed in the PP Set, including the RT-PCR and Elecsys results from the PDV, based on a total of 712 participants who had an asymptomatic SARS-CoV-2 infection starting 14 days after randomization (498 cases in the placebo group and 214 cases in the mRNA-1273 group). The VE point estimate based on the hazard ratio was 63.0%. This analysis confirms that vaccination with mRNA-1273 protects against asymptomatic infection (albeit at a lower VE than for symptomatic cases).

Immunogenicity Results: mRNA-1273 was highly immunogenic as measured by both bAb and nAb in both SARS-CoV-2 baseline-negative and baseline-positive individuals, as indicated by increased bAb and nAb levels 1 month after first injection (Day 29) and 1 month after second injection (Day 57).

Antibody levels at Day 29 in baseline-positive mRNA-1273 treated participants were similar to those observed at Day 57 in baseline-negative participants, indicating that the first injection of mRNA-1273 acts like a booster in participants with previous SARS-CoV-2 infection.

Among SARS-CoV-2 baseline-negative mRNA-1273 treated participants, seroresponse by bAb assay exceeded 99% at both Day 29 and Day 57, while seroresponse by nAb assay was 81.4% at Day 29 and 98.9% at Day 57.

Similar results were observed for subgroups stratified by age (≥ 18 to < 65 years and ≥ 65 years) in both SARS-CoV-2 baseline-negative and baseline-positive mRNA-1273 treated participants.

While vaccination with mRNA-1273 was highly immunogenic and protective against COVID-19, breakthrough cases occurred and there was no apparent bAb level or nAb titer through Day 57 that was predictive of the presence or absence of breakthrough COVID-19 cases.

Safety Results: In this final, randomized, blinded phase (Part A) analysis, the mRNA-1273 vaccine administered as 2 injections 28 days apart demonstrated an acceptable safety profile in the study population. This conclusion is supported by reactogenicity and key safety findings summarized here.

Solicited local and systemic adverse reactions were more frequent in mRNA-1273 than in placebo recipients, with most events considered grade 1 or 2 in severity, and most events in mRNA-1273 recipients occurring within 1 to 2 days and lasting a median of 1 to 3 days. The most common solicited local AR was pain, and the most commonly reported solicited systemic ARs were fatigue, headache, myalgia, and arthralgia. Older adults (≥ 65 years) had lower rates of solicited ARs than younger adults (< 65 years). Participants SARS-CoV-2 positive at baseline had rates of solicited ARs comparable to those among baseline negative participants. More mRNA-1273 recipients reported use of medication for pain or fever than placebo recipients, consistent with vaccine reactogenicity.

Unsolicited TEAEs in the 28 days after any injection occurred at similar rates in the mRNA-1273 and placebo groups. The higher rate of unsolicited TEAEs considered treatment-related by the investigator among mRNA-1273 participants was largely driven by events that mapped to solicited ARs but occurred beyond the solicited AR collection period or were ARs similar to solicited ARs. In addition, TEAEs were assessed for: (i) imbalances between study groups, and (ii) AEs of interest following COVID-19 vaccination or vaccinations in general. Imbalances were investigated based on the degree of imbalance and the biological plausibility and temporal occurrence relative to study treatment. An imbalance in the overall number of herpes zoster cases was noted, with more cases in the mRNA-1273 than in the placebo group; however, most cases in the mRNA-1273 group occurred more than 28 days after any dose and at an incidence expected in the general population. In contrast, most cases in the placebo group occurred within 28 days and at rates lower than expected of the general population. These findings are not supportive of relatedness to mRNA-1273.

Certain AEs are of theoretical interest for COVID-19 vaccines and were carefully assessed in the blinded study phase. mRNA-1273 vaccine was highly efficacious in preventing COVID-19 and severe COVID-19, and this efficacy has been sustained, dispelling concerns of VAERD. No significant clinical findings were identified from the SMQ/CMQ searches performed for the analyses of AEs of clinical interest for COVID-19 vaccines. A search (SMQ) for CNS vascular disorders identified a categorical imbalance, with 21 participants in the mRNA-1273 and 11 participants in the placebo group experiencing events in this SMQ, but the apparent imbalance was largely due to inclusion of 5 participants with subarachnoid hemorrhage and subdural hematoma (3 and 2 participants, respectively in the mRNA-1273 group and none in placebo) in this category. These latter events were mostly related to trauma and not to study treatment. Other

events of potential interest for COVID-19 vaccines are thrombotic and embolic events, for which no imbalance between groups was identified. Finally, assessments for TEAEs of myocarditis or pericarditis, or the symptoms suggestive of these diagnoses (including chest pain, dyspnea, and tachycardia) was performed. No events of myocarditis were identified. Pericarditis without concurrent myocarditis was reported as an SAE for 2 participants in each treatment group; the 2 events in the mRNA-1273 group occurred more than 28 days after second dose and in participants older than 55 years. Symptoms consistent with myocarditis or pericarditis were assessed, seeking patterns in grouping of symptoms or clustering in time, and only a single participant met a diagnosis of pericarditis. Assessment of events often associated with vaccination was performed, with a focus on hypersensitivity and anaphylaxis. Hypersensitivity events were more common among mRNA-1273 than placebo recipients; most of the imbalance derived from injection site urticaria and rashes. No anaphylaxis events were reported within 30 minutes after any injection.

In total, mRNA-1273 has a reactogenicity profile consistent with parenteral vaccination and generally well tolerated. Similarly, the safety profile is acceptable. No unexpected findings were identified in this final assessment of the randomized, blinded phase of the study.

Conclusions: This study was designed to evaluate the efficacy, safety, and immunogenicity of mRNA-1273 SARS-CoV-2 vaccine compared to placebo in adults 18 years of age and older who have no known history of SARS-CoV-2 infection but whose occupation or location and living circumstances put them at increased risk of acquiring COVID-19 and/or SARS-CoV-2 infection.

- The final efficacy analysis of the primary endpoint for Part A (04 May 2021) included 799 cases. The results of this analysis were consistent with the results of the interim and primary efficacy analyses, confirming persistent, high efficacy over a substantially larger case database and over a longer median observation period of over 5.3 months. For the final efficacy analysis, the VE point estimate was 93.2% ($p < 0.0001$) and within the 95% CIs of the VE point estimates for the interim and primary efficacy analyses.
    - Divergence of case incidence began early between mRNA-1273 and placebo groups, starting in the period from randomization up to14 days after the first injection. Thereafter, cumulative incidence rate for the placebo group increased steadily while it remained stable and low in the mRNA-1273 group for the remainder of the observation period.
    - Vaccine efficacy was consistent across subgroups for the primary efficacy endpoint.
    - Vaccine efficacy was also consistent across the secondary endpoints characterized by high VE point estimates and tight 95% CIs, with the lower bounds of the 95% CIs well above 30%.

- mRNA-1273 was highly immunogenic as measured by both bAb and nAb in both SARS-CoV-2 baseline-negative and baseline-positive individuals, as indicated by increased bAb and nAb levels 1 month after first injection (Day 29) and 1 month after second injection (Day 57).
- mRNA-1273 demonstrated an acceptable safety profile in the participant population enrolled in this study. mRNA-1273 has a reactogenicity profile consistent with parenteral vaccination and generally well tolerated. No unexpected findings were identified in this final assessment of the randomized, blinded phase of the study.

This report is based on the data from the randomized, placebo controlled, blinded phase (Part A) of the study. Data from Part B, in which eligible participants were offered open-label mRNA-1273, will be included in a CSR addendum.

Date and Version of This Report: Final, 05 August 2021

1 INTRODUCTION

1.1 Background

Coronaviruses (CoVs) are a large family of viruses that cause illness ranging from the common cold to more severe diseases, such as Middle East respiratory syndrome (MERS) and severe acute respiratory syndrome.

An outbreak of coronavirus disease 2019 (COVID-19) caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) began in Wuhan, Hubei Province, China in December 2019 and the disease has since spread globally (WHO 2020a). On 11 Mar 2020, the World Health Organization declared COVID-19 a pandemic. As of 02 May 2021, more than 151 million cases and over 3 million deaths worldwide have been attributed to the COVID-19 pandemic (WHO 2021), and in the United States, the US Centers for Disease Control and Prevention (CDC) reported over 32 million cases of COVID-19, with 578,993 total deaths (CDC 2021). The CDC have reported that the highest risk of disease burden is in older adults (≥ 65 years old) and people of any age who have certain underlying medical conditions such as cancer, chronic kidney disease, chronic obstructive pulmonary disease, serious heart conditions, immunocompromised state, obesity, pregnancy, sickle cell disease, and type 2 diabetes mellitus; smokers are also at increased risk for severe COVID-19 (CDC 2020a).

Global efforts to evaluate novel antivirals and therapeutic strategies to treat severe SARS-CoV-2 infections have intensified, and there is an urgent public health need for rapid development of novel prophylactic therapies, including vaccines, to prevent the spread of this disease.

ModernaTX, Inc. (Sponsor) has developed a rapid-response, proprietary vaccine platform based on a messenger RNA (mRNA) delivery system. The platform is based on the principle and observations that cells in vivo take up mRNA, translate it, and then express protein viral antigen(s) on the cell surface. The delivered mRNA does not enter the cellular nucleus or interact with the genome, is nonreplicating, and is expressed transiently. mRNA vaccines have been used to induce immune responses against infectious pathogens such as cytomegalovirus (NCT03382405), human metapneumovirus and parainfluenza virus type 3 (NCT03392389), Zika virus (NCT03325075), and influenza virus (NCT03076385 and NCT03345043).

The Sponsor has used its mRNA-based platform to develop a novel lipid nanoparticle (LNP)-encapsulated mRNA-based vaccine against SARS-CoV-2 (mRNA-1273). mRNA-1273 encodes for the full-length spike protein of SARS-CoV-2, modified to introduce 2 proline residues to stabilize the S-2P spike protein into a prefusion conformation. The CoV spike protein mediates attachment and entry of the virus into host cells (by fusion), making it a primary target for neutralizing antibodies (nAb) that prevent infection (Corti et al 2015; Wang et al 2015;

Yu et al 2015; Johnson et al 2016; Chen et al 2017; Wang et al 2018; Kim et al 2019; Widjaja et al 2019).

1.2 Nonclinical Studies

Nonclinical immunogenicity, biodistribution, and safety studies were completed by the Sponsor using mRNA-1273 or similar mRNA-based vaccines formulated in SM-102–containing LNPs.

The Sponsor performed nonclinical studies of mRNA-1273 in mice, hamsters, and nonhuman primates (NHPs) to evaluate vaccine-induced immune responses, protection from high-dose SARS-CoV-2 virus challenge, and to address the theoretical concern of enhanced respiratory disease mediated by vaccine-induced antibody responses and/or Th2-directed T-cell responses observed with other vaccines against viral respiratory diseases. These studies demonstrated that mRNA-1273 is immunogenic in all species assessed, showing a dose-dependent response in IgG binding antibody titers and a strong correlation between binding antibody (bAb) and nAb activity.

Dose levels were included that were predicted to be optimal (fully protective) and suboptimal (subprotective). At higher doses, mice and NHPs were fully protected from viral replication in both lungs and nasal passages. At subprotective dose levels, animals either remained fully protected in the lungs or had reduced viral burden post-challenge versus control animals. The fact that there were no observations of increased viral load in vaccinated animals at protective or subprotective dose levels, further supports that mRNA-1273 does not drive enhanced disease.

Antigen-specific T-cell responses were observed in studies in mice and in the NHP study. Th1-directed CD4 and CD8 T-cell responses were measured post-boost in animals that were vaccinated with mRNA-1273. Direct measurement of Th1-directed responses in mice and NHPs, indirect measurement of IgG2a/c/IgG1 antibody subclasses in mice, and the high levels of neutralizing antibody in all species lessens concerns regarding disease enhancement associated with administration of mRNA-1273.

Overall, animal studies demonstrated that mRNA-1273 is immunogenic, fully protects animals from challenge at optimal dose levels, and does not drive enhanced respiratory disease at protective or subprotective dose levels.

The pivotal submission-enabling toxicology studies were conducted with 5 mRNA vaccines that encode various antigens developed with the Sponsor's mRNA-based platform using SM-102-containing LNPs (2 Zika virus vaccines: mRNA-1706 and mRNA-1893; 1 hMPV and PIV3 vaccine: mRNA-1653; and 2 CMV vaccines: mRNA-1647 and mRNA-1443). The aggregate repeat-dose toxicity profile of mRNA vaccines that were developed with the Sponsor's mRNA-based platform in rats, at intramuscular (IM) doses ranging from 8.9 to 150 µg/dose

administered once every 2 weeks for up to 6 weeks, was similar and consistent despite the fact the different mRNA constructs encode different antigens. Therefore, the Sponsor proposes that the toxicity associated with mRNA vaccines formulated in similar LNPs is driven primarily by the LNP composition, and to a lesser extent, by the biologic activity of the antigens encoded by the mRNA; therefore, the aggregate Good Laboratory Practice repeat-dose rat data are considered to be representative of mRNA vaccines formulated in the same SM-102 LNPs and support the clinical development of mRNA-1273. In addition, a developmental and reproductive toxicity study to assess potential fertility and pre and postnatal development effects of mRNA-1273 in pregnant and lactating female Sprague Dawley rats was conducted at a clinically relevant dose. Maternal administration of mRNA-1273 (100 µg) before mating (2 doses) and during gestation (2 additional doses) did not have any adverse effects on the F_0 or F_1 generations. The mRNA related non-adverse effects were limited to an increase in the number of fetuses with common skeletal variations of 1 or more rib nodules and 1 or more wavy ribs with no effect on viability or growth and development of f1 generation. Strong maternal to fetal and maternal-to-pup transfer of antibodies was observed with mRNA-1273.

1.3 Other Clinical Studies in the mRNA-1273 Development Plan

The clinical development of mRNA-1273 has been expedited to address the ongoing global public health emergency resulting from the SARS-CoV-2 pandemic (and assigned by the WHO to the highest public health emergency status). The studies were designed in accordance with both FDA general guidance on COVID-19 vaccine development (FDA 2020) and FDA product-specific guidance. These studies are also conducted in accordance with consensus ethical principles derived from international guidelines including the Declaration of Helsinki and Council for International Organizations of Medical Sciences (CIOMS) International Ethical Guidelines and applicable International Council for Harmonisation (ICH) Good Clinical Practice (GCP) Guidelines.

In addition to mRNA-1273-P301 (Study 301), multiple clinical studies of mRNA-1273 are ongoing to address the safety, immunogenicity, and/or efficacy of the vaccine. The initial safety and dose-finding portions of the clinical program have been completed in 3 studies (Study 20-0003, Study mRNA-1273-P201, and Study mRNA-1273-P301) and participants are continuing to be evaluated and followed for various purposes (ie, long-term safety, persistence of antibody responses, evaluation of a booster dose, etc.) No clinical studies have been completed with mRNA-1273.

Phase 1 DMID Study 20-0003 (NCT04283461) is an ongoing, dose-escalation, open-label study to assess the safety and immunogenicity of mRNA-1273 in healthy adults aged 18 years and older. Study 101 is sponsored by the Division of Microbiology and Infectious Diseases

(DMID) of the National Institute of Allergy and Infectious Diseases (NIAID). The study includes a total of 10 cohorts. Participants received 2 injections of 25 µg, 50 µg, 100 µg, or 250 µg of mRNA-1273. As a control, a panel of convalescent sera was obtained from 41 patients recovering from COVID-19 and was used as a benchmark immunogenicity comparator for antibodies induced by natural SARS-CoV-2 infection. Blood sample collection time points include baseline, Days 8, 15, 29 (prior to injection 2), 36, 43, and 57, as well as 3, 6, and 12 months after the second vaccination (Days 119, 209, and 394, respectively). Interim results from 45 participants, 18 to 55 years of age, who received 2 doses of 25, 100, and 250 µg have been published (Jackson et al 2020). Data on 40 older adults ≥ 56 years of age who received 2 doses of either 25 or 100 µg in the same Phase 1 DMID study were also published (Anderson et al 2020).

Interim results from 120 participants (age cohorts 18 to 55 years, 56 to 70 years, and ≥ 71 years; data cutoff 07 Oct 2020) showed that mRNA-1273, administered as 2 doses 28 days apart was safe and immunogenic in healthy adult participants aged ≥ 18 years. After mRNA-1273 administration, fatigue, headache, myalgia, fever, and injection site pain were the most commonly reported solicited systemic and local adverse reactions (ARs), with higher incidence noted after the second injection than after the first injection for the solicited systemic ARs. Most of the solicited ARs were mild or moderate; severe solicited ARs predominantly occurred at the highest dose (250 µg). mRNA-1273 induced robust binding antibody responses (S-2P and receptor binding domain [RBD] specific) after 2 injections. Based on the results of safety and immunogenicity at data cutoff, the 100-µg dose provides promising immunogenicity results in adults of all ages with an acceptable safety profile and was the dose selected for further evaluation in the Phase 3 clinical study. Immunogenicity and safety data through Day 209 showed that the immune responses persisted and no safety concerns were found in the healthy adult participants aged ≥ 18 years through 6 months after the second dose of mRNA-1273.

An amendment to Study 101 added an optional third mRNA-1273 vaccination to potentially enhance and extend the duration of protection provided by the 2-dose vaccination schedule of mRNA-1273 administered in the main study, and to gain an understanding of the immune responses to a third dose of mRNA-1273. Substudy subjects will receive a third mRNA-1273 vaccination, administered via an IM injection at a dosage of 100 µg (0.5 mL), given 6 to 12 months after receipt of their second vaccination in the main study. Substudy subjects will be followed for safety, reactogenicity, and immunogenicity endpoints through 12 months after the third vaccination. To be eligible to participate in the substudy, subjects must have received both the first and second mRNA-1273 vaccinations in the main study.

Phase 2a Study mRNA-1273-P201 (NCT04405076) is an ongoing, blinded, randomized, placebo-controlled dose-finding study in adults 18 years and older. The study was designed to

confirm the dose (100 µg) to be advanced into the pivotal Phase 3 study based on the observed safety profile and immunogenicity in healthy adults. Two dose levels, 50 µg and 100 µg, are being evaluated in this study, based in part on initial safety data from the Phase 1 DMID study of mRNA-1273 (Study 20-0003). The study includes 2 age cohorts: Cohort 1 with 300 participants (18 to 55 years old) and Cohort 2 with 300 participants (≥ 55 years old). A total of 600 participants received either mRNA-1273 vaccine or saline placebo control according to a 1:1:1 randomization ratio; ie, within each age cohort, 100 participants received mRNA-1273 50 µg, 100 participants received mRNA-1273 100 µg, and 100 participants received saline placebo. Two doses were administered to each participant 28 days apart. The study was started with a parallel enrollment of all 300 participants in Cohort 1 (18 to 55 years old) and a sentinel group of 50 participants in Cohort 2 (≥ 55 years old); after review of the safety data by the independent safety monitoring committee (SMC), Cohort 2 was expanded to include the remaining 250 participants.

As of 05 Nov 2020, 200 (100%) participants each in the mRNA-1273 50 µg group, mRNA-1273 100 µg group, and placebo group received the first dose, and 195 (97.5%) participants in the mRNA-1273 50 µg group, 198 (99.0%) participants in the mRNA-1273 100 µg group, and 194 (97.0%) participants in the placebo group received the second injection (mRNA-1273-P201). No protocol-specified pause rules were met during the study. Vaccination with mRNA-1273 resulted in significant immune responses to SARS-CoV-2 with an acceptable safety profile in the participant population enrolled in this study at both dose levels in 2 age cohorts: Cohort 1 (18 to 55 years old) as well as Cohort 2 (≥ 55 years old), confirming the selection of the 100-µg dose that was brought forward in the pivotal Phase 3 study. Data through Day 209 are being analyzed at the time of this report.

An amendment to the Study 201 protocol adapted the study design to include open-label interventional phases (Part B and Part C). Part B allowed unblinding of participants and offered 2 injections of mRNA-1273 in an open label manner, 28 days apart, to all participants who received placebo in Part A. Part B also offered a single booster dose of mRNA-1273 (50 µg) to participants who received 1 or 2 doses of mRNA-1273 (50 µg or 100 µg) in Part A. Part C was prompted by the need to pro-actively prepare for vaccination strategies that induce broader protection, including against emerging variants of SARS-CoV-2 such as B.1.351. Part C enrolled participants from Study 301 who received 2 doses of mRNA-1273 100 µg, 28 day apart, at least 6 months prior. Part C participants received a single injection of mRNA-1273.351 (20 µg or 50 µg) or mRNA-1273.351 mixture (50 µg total – 25 µg of 1273 and 25 µg of .351).

Phase 2/3 Study mRNA-1273-P203 (NCT04649151) is an ongoing, Phase 2/3, randomized, observer-blind, placebo-controlled study being conducted to assess the safety and immunogenicity (to infer the effectiveness) of mRNA-1273 in an adolescent population aged

12 to < 18 years. The study includes 2 arms: 100 µg of mRNA-1273 and placebo. Approximately 3,000 participants between 12 to < 18 years of age were randomly assigned in a 2:1 ratio to receive mRNA-1273 (n=2,000) or placebo (n=1,000). All participants are being monitored for 12 months following the second dose of vaccine or placebo to enable assessment of safety and immunogenicity.

Phase 2/3 Study mRNA-1273-P204 (NCT04796896) is an ongoing Phase 2/3 two-part study with an open-label, dose-escalation and age de-escalation (Part 1) and a randomized, observer-blind, placebo-controlled expansion (Part 2) to evaluate the safety, tolerability, reactogenicity, and immunogenicity (to infer the effectiveness) of mRNA-1273 in healthy children aged 6 months to < 12 years, divided into 3 age groups (6 to < 12 years, 2 to < 6 years, and 6 months to < 2 years). Enrollment of approximately 6,750 participants (1,275 participants in Part 1 and 5,700 participants in Part 2) is planned. Up to 3 dose levels of mRNA-1273 (25, 50, and 100 µg) will be evaluated in Part 1, with the highest number enrolled in the oldest age group, and the final dose level selected will be administered in 3:1 ratio (mRNA-1273:placebo) to approximately 5,700 participants (approximately 1,700 participants in the 6 to < 12 years of age group and approximately 2,000 participants in both the 2 to < 6 years and the 6 months to < 2 years age groups) in Part 2.

Phase 3b Study mRNA-1273-P304 (NCT04860297) is an ongoing Phase 3b open-label safety and immunogenicity study of mRNA-1273 in adult solid organ transplant recipients and healthy control participants who are at least 18 years of age. Approximately 240 participants (110 kidney transplant recipients, 110 liver transplant recipients, and 20 healthy adults) are planned to be enrolled and receive 2 doses of mRNA-1273 100 µg 28 days apart.

Recent data based on post-Emergency Use Authorization (EUA) experience show that solid organ transplant recipients' immune response to mRNA-based vaccination has been substantially lower than what has been reported in the general population, with antibody responses detectable in only 30-60% after 2 doses (Benotmane et al 2021; Boyarsky et al 2021, Grupper et al 2021; Marinaki et al 2021). Therefore, an amendment to Study 304 changed the study design so that all solid organ transplant recipients will be offered the opportunity to receive a third dose of 100 µg mRNA-1273 vaccine on Day 85.

1.4 Study Rationale

Study mRNA-1273-P301 was designed as a Phase 3, randomized, stratified, observer-blind, placebo-controlled study to evaluate the efficacy, safety, and immunogenicity of mRNA-1273 SARS-CoV-2 vaccine compared to placebo in adults 18 years of age and older who have no known history of SARS-CoV-2 infection but whose occupation or location and living

circumstances put them at increased risk of acquiring COVID-19 and/or SARS-CoV-2 infection. The primary goals of this Phase 3 study are to evaluate the vaccine efficacy (VE) of mRNA-1273 to prevent COVID-19, compared to placebo and to further evaluate the safety and reactogenicity profile of mRNA-1273.

The Study 301 protocol and statistical analysis plan (SAP) were designed in accordance with both FDA general guidance on COVID-19 vaccine development (FDA 2020) and FDA product-specific guidance. Study P301 data were extensively discussed with European Medicines Agency, Health Canada, as well as other agencies as part of the authorization pathway developed to expedite regulatory approval in each country. Study 301 was conducted with oversight by an independent Data and Safety Monitoring Board (DSMB) (Section 3.8.4.2) and also a clinical endpoint adjudication committee that reviewed potential cases of COVID-19 (Section 3.8.4.3). The study was conducted in accordance with consensus ethical principles derived from international guidelines including the Declaration of Helsinki and CIOMS International Ethical Guidelines and applicable ICH GCP Guidelines (Section 3.4.2).

2 STUDY OBJECTIVES AND ENDPOINTS

The study objectives and endpoints are presented in Table 2-1.

Table 2-1: Objectives and Endpoints

Objectives	Endpoints
Primary efficacy	

• To demonstrate the efficacy of mRNA-1273 to prevent COVID-19.	• The VE of mRNA-1273 to prevent the first occurrence of COVID-19 starting 14 days after the second dose of IP, where COVID-19 was defined as symptomatic disease based on the following criteria:
	  • The participant must have experienced at least TWO of the following systemic symptoms: fever (≥ 38ºC), chills, myalgia, headache, sore throat, new olfactory and taste disorder(s), OR
	  • The participant must have experienced at least ONE of the following respiratory signs/symptoms: cough, shortness of breath or difficulty breathing, OR clinical or radiographical evidence of pneumonia; AND
	  • The participant must have at least 1 NP swab, nasal swab, or saliva sample (or respiratory sample, if hospitalized) positive for SARS-CoV-2 by RT-PCR.

Primary safety	
• To evaluate the safety and reactogenicity of 2 injections of the mRNA-1273 vaccine given 28 days apart.	• Solicited local and systemic ARs through 7 days after each dose of IP. • Unsolicited AEs through 28 days after each dose of IP. • MAAEs or AEs leading to withdrawal through the entire study period. • SAEs throughout the entire study period.

Objectives	Endpoints
Secondary efficacy	
• To evaluate the efficacy of mRNA-1273 to prevent severe COVID-19.	• The VE of mRNA-1273 to prevent severe COVID-19, defined as first occurrence of COVID-19 starting 14 days after the second injection of IP, (as per the primary endpoint) AND any of the following: • Clinical signs indicative of severe systemic illness, respiratory rate ≥ 30 per minute, heart rate ≥ 125 beats per minute, $SpO_2 \leq 93\%$ on room air at sea level, or PaO_2/FIO_2 < 300 mm Hg, OR • Respiratory failure or ARDS (defined as needing high-flow oxygen, non-invasive or mechanical ventilation, or ECMO), evidence of shock (systolic BP < 90 mm Hg, diastolic BP < 60 mm Hg, or requiring vasopressors), OR • Significant acute renal, hepatic, or neurologic dysfunction, OR • Admission to an intensive care unit or death.
• To evaluate the efficacy of mRNA-1273 to prevent serologically confirmed SARS-CoV-2 infection or COVID-19 regardless of symptomatology or severity.	• The VE of mRNA-1273 to prevent the first occurrence of either COVID-19 or SARS-CoV-2 infection starting 14 days after the second injection of IP. This endpoint includes COVID-19, as defined for the primary endpoint, and asymptomatic SARS-CoV-2 infection, determined by seroconversion assessed by bAb levels against SARS-CoV-2 as measured by a ligand-binding assay specific to the SARS-CoV-2 nucleocapsid protein or a positive RT-PCR test post baseline. This endpoint was evaluated in participants who were SARS-CoV-2 negative at baseline.
• To evaluate VE against a secondary definition of COVID-19.	• The VE of mRNA-1273 to prevent the secondary case definition of COVID-19 starting 14 days after the second injection of IP. The secondary case definition of COVID-19 was defined as the presence of at least 1 of the following systemic symptoms: fever (temperature ≥ 38ºC), or chills, cough, shortness of breath or difficulty breathing, fatigue, muscle aches or body aches, headache, new loss of taste or smell, sore throat, nasal congestion or rhinorrhea, nausea or vomiting, or diarrhea AND a positive NP swab, nasal swab, or saliva sample (or respiratory sample, if hospitalized) for SARS-CoV-2 by RT-PCR.
• To evaluate VE to prevent death caused by COVID-19.	• The VE of mRNA-1273 to prevent death due to a cause directly attributed to a complication of COVID-19, starting 14 days after the second injection of IP.

Objectives	Endpoints
• To evaluate the efficacy of mRNA-1273 to prevent COVID-19 after the first dose of IP.	• The VE of mRNA-1273 to prevent the first occurrence of COVID-19 starting 14 days after the first injection of IP.
• To evaluate the efficacy of mRNA-1273 to prevent COVID-19 in all study participants, regardless of evidence of prior SARS-CoV-2 infection.	• The VE of mRNA-1273 to prevent the first occurrence of COVID-19 starting 14 days after the second injection of IP regardless of evidence of prior SARS-CoV-2 infection (FAS analysis population).
• To evaluate the efficacy of mRNA-1273 to prevent asymptomatic SARS-CoV-2 infection.	• The VE to prevent the first occurrence of SARS-CoV-2 infection in the absence of symptoms defining COVID-19 starting 14 days after the second injection of IP. SARS-CoV-2 infection was determined by seroconversion assessed by bAb levels against SARS-CoV-2 as measured by a ligand-binding assay specific to the SARS-CoV-2 nucleocapsid protein or a positive RT-PCR test at a scheduled visit (eg, predose on Day 29). This endpoint was evaluated in participants who were SARS-CoV-2 negative at baseline.
Secondary immunogenicity	
• To evaluate the immunogenicity of 2 doses of mRNA-1273 given 28 days apart.	• GMT of SARS-CoV-2 -specific nAb on Day 1, Day 29, Day 57, Day 209, Day 394, and Day 759[a]. • GMFR of SARS-CoV-2-specific nAb relative to Day 1 on Day 29, Day 57, Day 209, Day 394, and Day 759[a]. • Quantified levels or GMT of S protein-specific bAb on Day 1, Day 29, Day 57, Day 209, Day 394, and Day 759[a]. • GMFR of S protein-specific bAb relative to Day 1 on Day 29, Day 57, Day 209, Day 394, and Day 759[a].
Exploratory - The following exploratory objectives and endpoints are addressed in this CSR:	
• To evaluate the effect of mRNA-1273 on the viral infection kinetics as measured by viral load at SARS-CoV-2 infection diagnosis by RT-PCR and number of days from the estimated date of SARS-CoV-2 infection until undetectable SARS-CoV-2 infection by RT-PCR.	• The VE of mRNA-1273 on the viral infection kinetics as measured by viral load at SARS-CoV-2 infection diagnosis by RT-PCR and number of days from the estimated date of SARS-CoV-2 infection until undetectable SARS-CoV-2 infection by RT-PCR.
• To assess VE to reduce the duration of symptoms of COVID-19.	• The VE of mRNA-1273 to reduce duration of COVID-19 symptoms.
• To evaluate VE against all-cause mortality.	• The VE of mRNA-1273 against all-cause mortality.
• To assess VE against BOD due to COVID-19	• The VE of mRNA-1273 against BOD based on the post SARS-CoV-2 infection follow-up.
• To evaluate the genetic and/or phenotypic relationships of isolated SARS-CoV-2 strains to the vaccine sequence.	• The genetic and/or phenotypic relationships of isolated SARS-CoV-2 strains to the vaccine sequence.
• To conduct additional analyses related to furthering the understanding of SARS-CoV-2 infection and COVID-19, including analyses	• Additional analyses related to furthering the understanding of SARS-CoV-2 infection and

Objectives	Endpoints
related to the immunology of this or other vaccines, detection of viral infection, and clinical conduct.	COVID-19, including analyses related to the immunology of this or other vaccines, detection of viral infection, and clinical conduct.

Abbreviations: AE = adverse event; AR = adverse reaction; ARDS = acute respiratory distress syndrome; bAb = binding antibody; BOD = burden of disease; BP = blood pressure; CSR = clinical study report; ECMO = extracorporeal membrane oxygenation; FAS = Full Analysis Set; FIO_2 = fraction of inspired oxygen; GMFR = geometric mean fold rise; GMT = geometric mean titer; IP = investigational product; MAAE = medically-attended adverse event; nAb = neutralizing antibody; NP = nasopharyngeal; PaO_2 = partial pressure of oxygen; RT-PCR = reverse transcription polymerase chain reaction; SAE = serious adverse event; SpO_2 = oxygen saturation by pulse oximeter; VE = vaccine efficacy.

[a] This Part A CSR presents the immunogenicity endpoints through Day 57 for the Per-Protocol Random Subcohort for Immunogenicity.

3 INVESTIGATIONAL PLAN

3.1 Overall Study Design and Plan

This is an ongoing 2-part Phase 3 study: Part A and Part B. Participants in Part A, the randomized, placebo-controlled, blinded phase of this study, were blinded to their treatment assignment. Given that the primary efficacy endpoint for mRNA-1273 against COVID-19 was met per the protocol-defined interim analysis (IA), Part B, the Open-Label Observational Phase of this study, was designed to offer participants who received placebo in Part A of this study and who met EUA eligibility, an option to request open-label mRNA-1273 during a Participant Decision Visit (PDV) (Figure 3-1).

All participants may have had up to 8 scheduled clinic visits, including Screening, Day 1, Day 29, Day 57, Day 209, Day 394, Day 759, and the PDV as specified in the Schedule of Events (SoE; mRNA-1273-P301 Clinical Study Protocol Table 16 [Vaccination Phase, Day 1 - Day 57], Table 17 [Surveillance Phase, Day 64 - Day 394], Table 18 [Surveillance Phase, Day 401 - Day 759], Table 19 [Convalescent Period, Starting with the Illness Visit], and Table 20 [Part B: Participant Decision Clinic Visit]; Appendix 16.1.1).

This Part A clinical study report (CSR) presents the data from the randomized, placebo-controlled, blinded phase (Part A) of the study based on the database lock on 04 May 2021, and includes available participant level data up to early unblinding, study discontinuation, the Part B PDV (Section 3.1.2) or data cutoff date (26 Mar 2021), whichever was earlier. Data from Part B, in which eligible participants were offered open-label mRNA-1273, will be included in a CSR addendum.

3.1.1 Part A, the Randomized, Placebo-Controlled, Blinded Phase

Part A of this study was a Phase 3, randomized, stratified, observer-blind, placebo-controlled study to evaluate the efficacy, safety, and immunogenicity of mRNA-1273 SARS-CoV-2 vaccine compared to placebo in adults 18 years of age and older who had no known history of SARS-CoV-2 infection but whose occupation or locations and living circumstances put them at appreciable risk of acquiring COVID-19 and/or SARS-CoV-2 infection.

Approximately 30,000 participants were randomly assigned to receive doses of either 100 µg of mRNA-1273 vaccine or placebo in a 1:1 randomization ratio. Assignment was stratified by age and health risk (Section 3.6.3). This was a case-driven study and thus final sample size was dependent on the actual attack rate of COVID-19.

All participants were assessed for efficacy and safety endpoints. A nasopharyngeal (NP) swab sample and blood sample were obtained from each participant before the first and second dose of

investigational product (IP). In addition, a series of postdose blood samples for immunogenicity are being collected through 24 months after the second dose of IP. Efficacy assessments included surveillance for COVID-19 with reverse transcriptase polymerase chain reaction (RT-PCR) confirmation of SARS-CoV-2 infection after the first and second dose of IP.

Each participant received 2 doses of IP by 0.5 mL intramuscular (IM) injection, the first on Day 1 and the second on Day 29. An NP swab sample was collected prior to the first and second dose of IP for evaluation by RT-PCR. To preserve observer blinding, only delegated unblinded study site personnel responsible for IP preparation, administration, and/or accountability had knowledge of study treatment assignment (Section 3.6.4).

Participants were given an electronic diary (eDiary) to report solicited ARs for 7 days after each dose of IP and to prompt an unscheduled clinic visit for clinical evaluation and NP swab sample if a participant experienced any symptoms of COVID-19. Participants used the eDiary to report solicited ARs for the first 7 days after each dose of IP (or until resolution for solicited ARs that continued beyond 7 days) and were then followed by weekly eDiary prompts (every 7 days) to elicit an unscheduled Illness Visit if the participant experienced COVID-19 symptoms. All participants received safety calls on Day 8, Day 15, Day 22, Day 36, and Day 43 that served both to monitor for unsolicited adverse events (AEs) and to monitor for symptoms of COVID-19.

Safety telephone calls and eDiary safety prompts were performed in conjunction with surveillance for COVID-19 according to the SoEs and were intended to capture serious AEs (SAEs), MAAEs, AEs leading to withdrawal, concomitant medications associated with these events, receipt of non-study vaccinations, and pregnancy (Section 3.7.1.2). If an eDiary prompt resulted in identification of a relevant safety event, a follow-up safety call was triggered.

Surveillance for signs and symptoms of COVID-19 is being performed through weekly contacts with the participant via a combination of telephone calls and completion of specific eDiary prompts starting at Day 1 through the end of the study (Section 3.7.1). Participants with symptoms of COVID-19 lasting at least 48 hours (except for fever and/or respiratory symptoms) returned to the clinic or were visited at home by medically qualified study site personnel within 72 hours to collect an NP swab sample for RT-PCR testing for SARS-CoV-2 and other respiratory pathogens, or alternatively, if a clinic or home visit was not possible, submitted a saliva (or nasal swab) sample for SARS-CoV-2 RT-PCR testing (Section 3.7.2).

All study participants who experienced COVID-19 symptoms and subsequently presented for an Illness Visit (in clinic or at home) were given an instruction card listing symptoms and severity grading system along with a thermometer, an oxygen saturation monitor, and saliva collection tubes. Study participants were contacted by the investigator (or appropriately delegated study site personnel) daily with telemedicine visits through Day 14 or until symptoms had resolved,

whichever was later. During the telemedicine visit (preferably done in the evening), the participant was asked to verbally report the severity of each symptom, their highest body temperature and lowest oxygen saturation for that day, and the investigator determined if medical attention was required due to worsening of COVID-19 symptoms. Study participants collected their own saliva (or nasal swab) sample at 3, 5, 7, 9, 14, and 21 days after the initial Illness Visit meeting criteria for COVID-19 (defined as the date of onset of symptoms and positive virologic test). Finally, a Convalescent Visit was scheduled approximately 28 days after the initial Illness Visit. At this visit, a saliva (or nasal swab) sample was collected and a blood sample was drawn for immunologic assessment of SARS-CoV-2 infection.

At each IP injection visit, participants were instructed (Day 1) or reminded (Day 29) on how to document and report solicited ARs in the eDiary provided. Solicited ARs were assessed for 7 days after each IP injection (or until resolution for solicited ARs that continued beyond 7 days), and unsolicited AEs were assessed for 28 days after each injection; SAEs, MAAEs, and AEs leading to withdrawal were assessed throughout the study.

Participants may have experienced AEs that necessitated an unscheduled visit. There may have also been situations in which the investigator asked a participant to report for an unscheduled visit following the report of an AE. Additional examinations may have been conducted at these visits as necessary to ensure the safety and well-being of participants during the study. Electronic case report forms (eCRFs) should have been completed for each unscheduled visit.

3.1.2 Part B, the Open-Label Observational Phase

The Part B Open-Label Observational Phase of the study was prompted by the authorization of a COVID-19 vaccine under EUA. Transitioning the study to Part B permitted all ongoing study participants to be informed of the availability and eligibility criteria of any COVID-19 vaccine made available under an EUA and the option to offer all ongoing study participants who request unblinding, an opportunity to schedule a PDV to know their original treatment assignment (placebo vs. mRNA-1273 vaccine). The Part B Open-Label Observation Phase also provided the opportunity for EUA-eligible study participants who previously received placebo to actively request to receive 2 doses of mRNA-1273 vaccine.

All participants in Part A were to proceed to Part B, starting with a PDV, at which time participants were given the option to be unblinded to their original group assignment.

The following participants were to continue with the original study SoEs:

- Participants who requested to not be unblinded,
- Participants who requested to be unblinded and received mRNA-1273, and

- Participants who requested to be unblinded and received placebo and choose to remain on placebo.

Participants who were unblinded, received placebo in Part A, were EUA eligible, and requested to receive mRNA-1273 are planned to have the following additional clinic visits as shown in the Supplemental SoE (mRNA-1273-P301 Clinical Study Protocol Table 21 [Appendix 16.1.1]):

- Open-Label Dose 1 (OL-D1): occurred at the PDV or at a scheduled subsequent visit.
- Open-Label Dose 2 (OL-D29): occurred 28 days after Dose 1 on OL-D1.
- Open-Label Clinic Visit (OL-D57): occurred 1 month after Dose 2 on OL-D29.

Participants who were unblinded, received only 1 dose of mRNA-1273 in Part A, were EUA eligible, and requested to receive mRNA-1273 are planned to have the following additional clinic visits as shown in the Modified Supplemental SoE (mRNA-1273-P301 Clinical Study Protocol Table 22 [Appendix 16.1.1]):

- Their second dose on OL-D1: occurred at the PDV or at a scheduled subsequent visit.
- Open-Label Clinic Visit (OL-D29): occurred 1 month after Dose 2 on OL-D1.

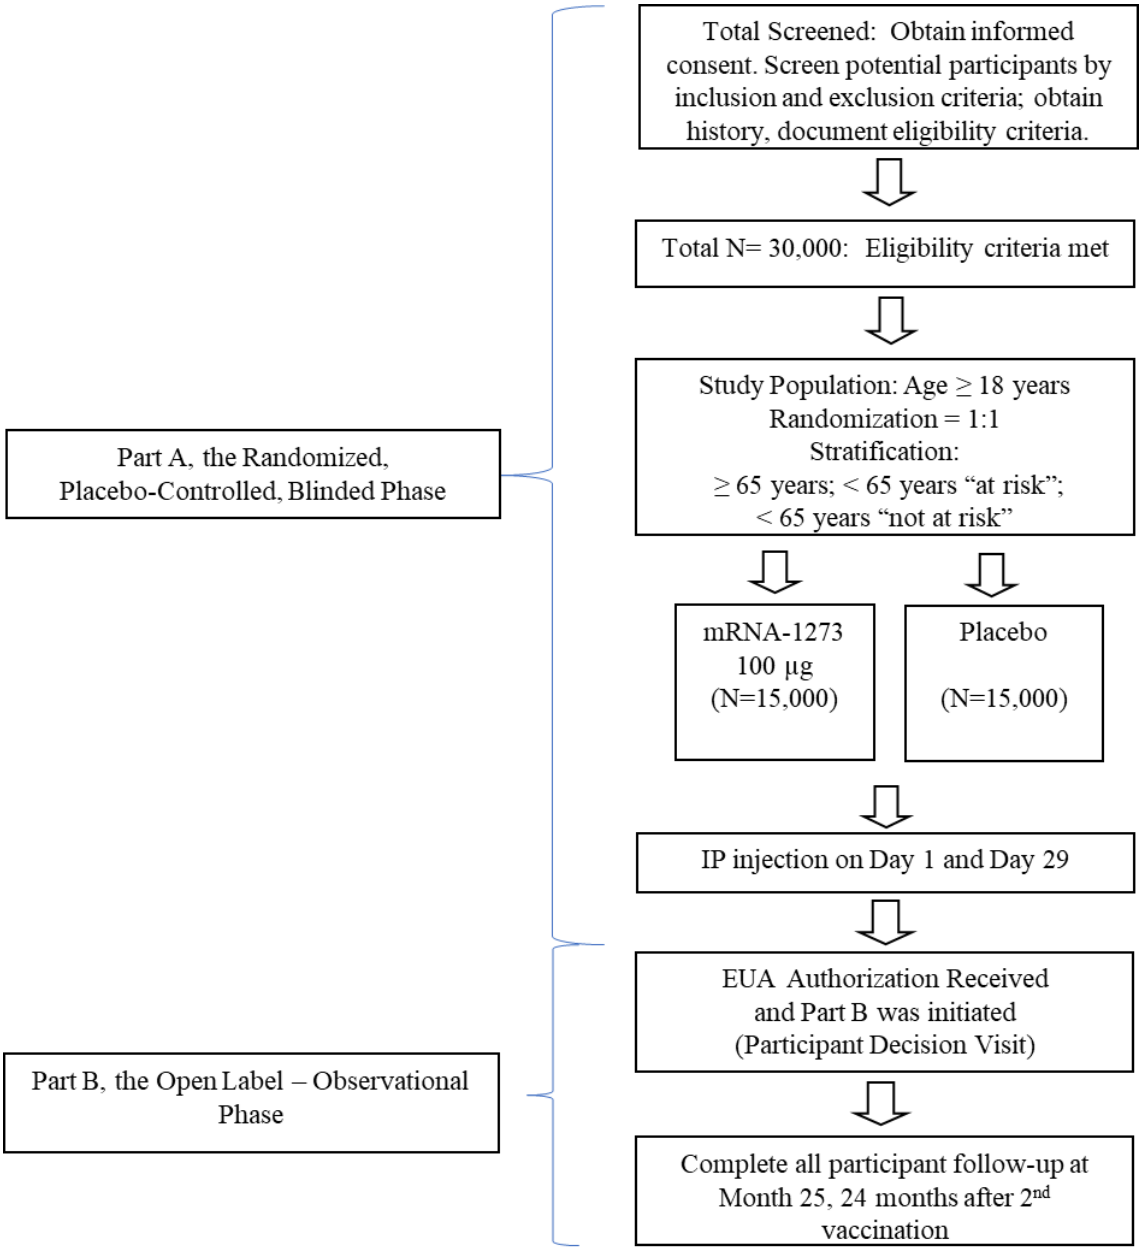
Participants receiving only 1 dose of mRNA-1273 in Part A were eligible to receive the second dose of mRNA-1273 under the following circumstances:

- They had a dosing error in Part A of the study that resulted in 1 dose of mRNA-1273 and 1 dose of placebo being administered.
- They did not have an AE that contraindicated the second dose of mRNA-1273 in Part A of the study.
- They did not withdraw consent in Part A of the study.
- They did not complete their second dose in Part A of the study for reasons other than the above.

All participants are expected to complete 24 months of follow-up after the second injection; study participants who entered the Supplemental or Modified Supplemental SoE did so in addition to their original SoE. Accordingly, all study participants are planned to complete the full study follow-up to 24 months after the second injection in Part A (mRNA-1273 or placebo).

A summary of the data from Part B, including COVID-19 cases, SAEs, AEs leading to withdrawal, MAAEs, and pregnancies will be included in a CSR addendum.

Figure 3-1: Study Flow Diagram: Part A, the Randomized, Placebo-Controlled, Blinded Phase, Followed by Part B, the Open-Label Observational Phase



Abbreviations: EUA = Emergency Use Authorization; IP = investigational product.

3.1.3 Discussion of Study Design

The mRNA-1273 vaccine is being developed to prevent COVID-19, the disease resulting from SARS-CoV-2 infection. The study was designed to primarily evaluate the clinical efficacy and safety of mRNA-1273 to prevent COVID-19 for up to 2 years after the second dose of

mRNA-1273. The immunogenicity endpoints and detection of SARS-CoV-2 infection are secondary objectives.

The design and focus of the study were dependent on the current COVID-19 pandemic, requiring identification of participant candidates at increased risk of SARS-CoV-2 infection. Adults at risk of SARS-CoV-2 infection who had no known history of SARS-CoV-2 infection were the planned target population. Potential study participants at increased risk of complications from COVID-19 were also included since it was hypothesized that these participants might benefit most from a vaccine. Participants ≥ 65 years of age, at increased risk of complications from COVID-19 due to their age, were also eligible for enrollment regardless of underlying medical conditions further increasing their risk of severe COVID-19.

Given the disproportionate disease burden of COVID-19 in racial and ethnic minorities, the study also aimed to enroll a representative sample of participants from these minority populations and adjust site selection and enrollment accordingly, per the Food and Drug Administration (FDA) Draft Guidance "Enhancing the Diversity of Clinical Trial Populations - Eligibility Criteria, Enrollment Practices, and Trial Designs" (June, 2019). Study sites were also selected on the basis of SARS-CoV-2 infection risk of the local population.

The dose selected for this study (100 µg of mRNA-1273) was based on assessment of available safety and immunogenicity data from Phase 1 studies of mRNA-1647 (NCT03382405), the DMID study 20-0003 entitled "Phase I, Open-Label, Dose-Ranging Study of the Safety and Immunogenicity of 2019-nCoV Vaccine (mRNA-1273) in Healthy Adults" (NCT04283461), and the Phase 2 mRNA-1273-P201 study. The schedule (2 doses administered 28 days apart) was used in these studies.

There was no licensed SARS-CoV-2 vaccine at the time of study initiation; accordingly, 0.9% sodium chloride (normal saline) injection (USP) was used as a placebo control.

On 11 Dec 2020, the US FDA issued the first EUA to Pfizer-BioNTech for the prevention of COVID-19 caused by SARS-CoV-2 in individuals 16 years of age and older. On 18 Dec 2020, the US FDA granted EUA for the mRNA-1273 vaccine for the prevention of COVID-19. Following EUA approval of COVID-19 vaccines, there was an increase in withdrawals of EUA-eligible participants who opted to be immunized with authorized vaccines. The clinical protocol was subsequently amended to adapt the study design to a 2-part Phase 3 study: Part A and Part B. Part A was designed to evaluate the clinical efficacy and safety of mRNA-1273 to prevent COVID-19. Part B, the Open-Label Observational Phase of the study, was prompted by the EUA and permitted all ongoing study participants to (a) be informed of the availability and eligibility criteria of any COVID-19 vaccine made available under EUA and (b) the option to offer all ongoing study participants who request unblinding an opportunity to schedule a study

visit to know their original group assignment (placebo vs. mRNA-1273 vaccine). Part B also provided the opportunity for study participants who previously received placebo to actively request to receive 2 doses of mRNA-1273 vaccine, where their participation would have otherwise denied them the opportunity to receive a COVID-19 vaccine under EUA.

3.2 Protocol Amendments and Other Changes in the Conduct of the Study

3.2.1 Changes in the Conduct of the Study

Seven amendments were made to the original protocol, dated 15 Jun 2020. The original protocol and amendments 1 through 7 are provided in Appendix 16.1.1. The summary of major changes for each amendment is provided in Table 3-1.

Table 3-1: Summary of Major Changes Implemented With Each Protocol Amendment

Protocol Amendment	Summary of Major Changes
Protocol (15 Jun 2020)	Original
Amendment 1 (26 Jun 2020)	• Provided more intensive surveillance of symptoms and severity of cases of COVID-19 after the first dose of investigational product • Increased the frequency of telemedicine contacts during the Convalescent Period following the initial Illness Visit • Added monitoring of oxygen saturation to the Convalescent Period. • Increased the frequency of monitoring for SARS-CoV-2, using saliva as the preferred sample matrix after the Illness Visit during the Convalescent Period • Added a respiratory sample for hospitalized participants as a matrix for confirming the presence of SARS-CoV-2 • Broadened the definition for seroconversion at a participant level • Eliminated paper diaries, substituting an instruction card listing symptoms and a severity grading system to enhance the quality of data obtained by telemedicine contacts • Decreased the number of symptoms (to 1 of the 11 CDC symptoms) that would result in an Illness Visit • Expanded the scope of eDiary prompts and data collected during the Surveillance Phase

Protocol Amendment	Summary of Major Changes
Amendment 2 (31 Jul 2020)	• Provided more intensive surveillance of symptoms and severity of cases of COVID-19 after the first dose of investigational product • Added a Day 29 NP swab prior to Dose 2 • Changed the clinic visit at Month 4 to a safety call • Clarified symptom duration (> 48 hours) to trigger NP swab collection and investigator judgment whether to obtain an NP swab in the 7 days following vaccination due to overlap of solicited systemic symptoms and COVID-19 • Removed mention of continuous biometric monitoring • Removed the inclusion criterion regarding male contraception • Clarified language around influenza vaccination • Removed restriction on enrollment of participants with HIV infection • Added expedited reporting of confirmed COVID-19 cases • Added an Oversight Group • Updated description of monitoring for potential harm, including details on case counting for the purpose of harm monitoring to align with a DSMB analysis plan
Amendment 3 (20 Aug 2020)	• Added a sentence to describe the intent to enroll a representative sample of racial and ethnic minority participants in the study • Added clarification to exclusion criterion #11 to define the parameters based on screening CD4 count and viral load for exclusion of study participants • Removed “topical tacrolimus” from exclusion criterion #12 • Added HIV infection to the risk factors at Screening • Added collection of risk factors for complications of COVID-19 • Removed redundant bullet in the sample size determination • Removed safety analysis by serostatus • Removed the categories (White, non-White) from the Race Variable in the subgroup analysis • Removed “cessation of exogenous hormonal therapy” • Removed “using hormonal contraception” from postmenopausal female with high FSH levels
Amendment 4 (30 Sep 2020)	• Increased the upper limit for stratification of enrolled participants considered “at risk” at Screening to up to 50% from 40% • Updated the description of an intercurrent event (unrelated death) and its strategy
Amendment 5 (11 Nov 2020)	• Clarified the weekly schedule for eDiary prompts through Year 1 and Year 2 of follow-up • Added the Month 19 safety call

Protocol Amendment	Summary of Major Changes
Amendment 6 (23 Dec 2020)	• Added a "Participant Decision Clinic Visit" • Updated the study design to split the study into a Blinded Phase (Part A) and an Open-Label Observational Phase (Part B) • Updated the status of the ongoing clinical studies, including results of the interim analyses of this study • Added long-term efficacy analyses • Updated the benefit/risk assessment • Clarified eDiary safety prompts
Amendment 7 (10 Feb 2021)	• Clarified site unblinding at the Participant Decision Visit • Clarified requirements for Part B participants who received only 1 dose of mRNA-1273 during Part A • Updated presentation and storage conditions for vaccine • Clarified concomitant medication, eDiary, and blood sampling procedures during Part A and Part B • Removed collection of body mass index from the Participant Decision Visit • Updated maximum planned volume of blood collection for the complete study to include a range • Added suspected cases of anaphylaxis as an MAAE and requirement to report as an SAE • Clarified immunogenicity subset • Updated intercurrent events and estimands • Updated case count parameters for long-term efficacy analysis • Removed height and weight from open-label clinic visits and clarified that physical examination is symptom-directed

Abbreviations: CDC = Centers for Disease Control and Prevention; DSMB = Data and Safety Monitoring Board, eDiary = electronic diary; FSH = follicle-stimulating hormone; HIV = human immunodeficiency virus; MAAE = medically-attended adverse event; NP = nasopharyngeal; SAE = serious adverse event.

3.3 Investigators and Study Administrative Structure

ModernaTX, Inc. was the Sponsor of this clinical study. A total of 99 study sites in the United States enrolled at least 1 participant in the study. The first participant's first visit for this study was 27 Jul 2020. This study is ongoing; this Part A CSR includes available participant level data up to early unblinding, study discontinuation, the Part B PDV or data cutoff date (26 Mar 2021), whichever was earlier.

The contract research organization (CRO), PPD (Wilmington, North Carolina), was responsible for the following: biostatistics and programming (including generation of the randomization list), clinical site management, data management, data analytics, project management, safety monitoring, and medical writing and publishing.

Endpoint Clinical, Inc (San Francisco, California) managed the Interactive Response Technology (IRT) system used for participant randomization and to manage, track, order, and resupply mRNA-1273 and placebo for the study sites.

IQVIA (Durham, North Carolina) was responsible for SAE reconciliation, including individual case safety report collection, evaluation, safety database entry, regulatory reporting, development safety update reports, medical review, and literature surveillance.

Medidata (Pittston, Pennsylvania) supplied eDiaries either as an application downloaded on participants' smartphone or using a device, which was used both for collection of 7-day reactogenicity and weekly eDiary prompts to elicit an unscheduled Illness Visit.

The Sponsor supplied mRNA-1273 and PPD supplied placebo to the sites.

The following laboratories were used:

PPD Central Laboratory (Highland Heights, Kentucky):

- Screening serology
- Follicle-stimulating hormone (FSH) testing, if required
- Elecsys® Anti-SARS-CoV-2 immunoassay

Viracor Eurofins Laboratories (Lee's Summit, Missouri):

- SARS-CoV-2 reverse transcriptase quantitative PCR (RT-qPCR) testing in NP swab and saliva
- BioFire® respiratory panel screening
- Spike-gene Next Generation Sequencing (NGS) and Whole Genome Sequencing (WGS) assay by RT-PCR

PPD Vaccine Laboratory (Richmond, Virginia):

- Anti-SARS-CoV-2 nucleocapsid (N)-protein enzyme-linked immunosorbent assay (ELISA)
- Anti-SARS-CoV-2 S-2P ELISA

NIH NIAID Vaccine Immunology Program (VIP; Bethesda, Maryland):

- MesoScale Discovery (MSD) electrochemiluminescence multiplex assay

Duke University (Durham, North Carolina):

- SARS-CoV-2 S pseudotyped neutralization assay

Safety monitoring committees utilized in this study included a Protocol Safety Review Team (PSRT), independent Data and Safety Monitoring Board (DSMB), and Adjudication Committee (AC); details are provided in Section 3.8.4.

A list of all investigators and clinical sites and other administrative structure/information is provided in Appendix 16.1.4.

3.4 Ethical Considerations

3.4.1 Independent Ethics Committee or Institutional Review Board

The protocol, protocol amendments, informed consent form (ICF), IB, and other relevant documents (eg, advertisements) were submitted to an institutional review board (IRB) or independent ethics committee (IEC) by the investigator and reviewed and approved by the IRB/IEC before the study was initiated.

Any amendments to the protocol required IRB/IEC approval before implementation of changes made to the study design, except for changes necessary to eliminate an immediate hazard to study participants.

The list of IRBs and IECs are available in Appendix 16.1.3.

3.4.2 Ethical Conduct of the Study

This study was conducted in accordance with the protocol and with the consensus ethical principles derived from international guidelines including the Declaration of Helsinki and CIOMS International Ethical Guidelines, applicable ICH GCP guidelines, and with applicable laws and regulatory requirements.

3.4.3 Participant Information and Consent

Before performing any study procedures, all potential participants signed an ICF. The informed consent document(s) must have met the requirements of 21 CFR 50; local regulations; ICH guidelines; Health Insurance Portability and Accountability Act (HIPAA) requirements, where applicable; and the IRB/IEC or study center. All consent documents were approved by the appropriate IRB/IEC. The actual ICF used at each center may have differed, depending on local regulations and IRB/IEC requirements. However, all versions must have contained the standard information found in the sample ICF provided by the Sponsor. Any change to the content of the ICF must have been approved by the Sponsor and the IRB/IEC prior to the form being used.

If new information became available that may have been relevant to the participant's willingness to continue participation in the study, this would have been communicated to him or her in a

timely manner. Such information would have been provided via a revised ICF or an addendum to the original ICF.

A participant who was rescreened was not required to sign another ICF if the rescreening occurred within 28 days from the previous ICF signature date.

Additional details of the informed consent process are provided in the mRNA-1273-P301 Clinical Study Protocol Section 11.2.6 (Appendix 16.1.1).

3.5 Selection of Study Population

3.5.1 Inclusion Criteria

Participants were eligible to be included in the study only if all the following criteria applied:

1. Adults ≥ 18 years of age at time of consent, who were at high risk of SARS-CoV-2 infection, defined as adults whose locations or circumstances put them at appreciable risk of exposure to SARS-CoV-2 and COVID-19.
2. Understood and agreed to comply with the study procedures and provided written informed consent.
3. Able to comply with study procedures based on the assessment of the investigator.
4. Female participants of nonchildbearing potential could have been enrolled in the study. Nonchildbearing potential was defined as surgically sterile (history of bilateral tubal ligation, bilateral oophorectomy, hysterectomy) or postmenopausal (defined as amenorrhea for ≥ 12 consecutive months prior to Screening without an alternative medical cause). An FSH level may have been measured at the discretion of the investigator to confirm postmenopausal status.
5. Female participants of childbearing potential could have been enrolled in the study if the participant fulfilled all the following criteria:
    - Had a negative pregnancy test at Screening and on the day of the first dose (Day 1).
    - Had practiced adequate contraception or had abstained from all activities that could result in pregnancy for at least 28 days prior to the first dose (Day 1).
    - Had agreed to continue adequate contraception through 3 months following the second dose (Day 29).
    - Was not currently breastfeeding

Adequate female contraception was defined as consistent and correct use of an FDA-approved contraceptive method in accordance with the product label. For example:

- Barrier method (such as condoms, diaphragm, or cervical cap) used in conjunction with spermicide
- Intrauterine device
- Prescription hormonal contraceptive taken or administered via oral (pill), transdermal (patch), subdermal, or IM route
- Sterilization of a female participant's monogamous male partner prior to entry into the study

Note: periodic abstinence (eg, calendar, ovulation, symptothermal, post-ovulation methods) and withdrawal were not acceptable methods of contraception.

6. Healthy adults or adults with pre-existing medical conditions who were in stable condition. A stable medical condition was defined as disease not requiring significant change in therapy or hospitalization for worsening disease during the 3 months before enrollment.

3.5.2 Exclusion Criteria

Participants were excluded from the study if any of the following criteria applied:

1. Was acutely ill or febrile 72 hours prior to or at Screening. Fever was defined as a body temperature ≥ 38.0°C/100.4°F. Participants who met this criterion may have been rescheduled within the relevant window periods. Afebrile participants with minor illnesses could have been enrolled at the discretion of the investigator.
2. Was pregnant or breastfeeding.
3. (Part A only) Had known history of SARS-CoV-2 infection.
4. Had prior administration of an investigational coronavirus (SARS-CoV, MERS-CoV) vaccine or current/planned simultaneous participation in another interventional study to prevent or treat COVID-19.
5. (Part A only) Demonstrated inability to comply with the study procedures.
6. (Part A only) Had an immediate family member or household member of this study's personnel.
7. Had known or suspected allergy or history of anaphylaxis, urticaria, or other significant AR to the vaccine or its excipients.

8. Had a bleeding disorder that was considered a contraindication to IM injection or phlebotomy.
9. Had received or planned to receive a non-study vaccine within 28 days prior to or after any dose of IP (except for seasonal influenza vaccine which was not permitted within 14 days before or after any dose of IP).
10. Had participated in an interventional clinical study within 28 days prior to the day of enrollment.
11. Had immunosuppressive or immunodeficient state, asplenia, recurrent severe infections (human immunodeficiency virus [HIV]-positive participants with CD4 count ≥ 350 cells/mm^3 and an undetectable HIV viral load within the past year [low level variations from 50-500 viral copies which did not lead to changes in antiretroviral therapy [ART] were permitted]).
12. Had received systemic immunosuppressants or immune-modifying drugs for > 14 days in total within 6 months prior to Screening (for corticosteroids ≥ 20 mg/day of prednisone equivalent).
13. Had received systemic immunoglobulins or blood products within 3 months prior to the day of Screening.
14. Had donated ≥ 450 mL of blood products within 28 days prior to Screening.

3.5.3 Withdrawal of Participants From the Study or Study Treatment

3.5.3.1 Participant Withdrawal From the Study

Participants who withdrew from the study were not replaced. A “withdrawal” from the study referred to a situation wherein a participant did not return for the final visit planned in the protocol.

Participants could have withdrawn consent and withdrawn from the study at any time, for any reason, without prejudice to further treatment the participant may have needed to receive. The investigator requested that the study participant complete all study procedures pending at the time of withdrawal.

If a participant desired to withdraw from the study because of an AE, the investigator tried to obtain agreement to follow up with the participant until the event was considered resolved or stable and then completed the end-of-study eCRF.

Information related to the withdrawal was documented in the eCRF. The investigator documented whether the decision to withdraw a participant from the study was made by the participant or by the investigator, as well as which of the following possible reasons was responsible for withdrawal:

- AE (specify)
- SAE (specify)
- Death
- Lost to follow-up
- Physician decision (specify)
- Pregnancy
- Protocol deviation
- Study terminated by Sponsor
- Withdrawal of consent by participant (specify); specify); this included participants who, at the PDV, withdrew consent from continuing in the study
- Other (specify)

Participants who were withdrawn from the study because of AEs (including SAEs) must have been clearly distinguished from participants who were withdrawn for other reasons. Investigators followed up with participants who were withdrawn from the study as result of an SAE or AE until resolution of the event.

Participants who were confirmed to have received placebo upon unblinding and intended to receive a COVID-19 vaccine under an EUA outside of this study were to be withdrawn from the study.

A participant withdrawing from the study may have requested destruction of any samples taken and not tested, and the investigator must have documented this in the site study records.

If the participant withdrew consent for disclosure of future information, the Sponsor could have retained and continued to use any data collected before such a withdrawal of consent.

The Sponsor continued to retain and use all research results that had already been collected for the study evaluation, unless the participant had requested destruction of these samples. All biological samples that had already been collected could be retained and analyzed at a later date (or as permitted by local regulations).

A participant was considered lost to follow-up if they repeatedly failed to return for scheduled visits without stating an intention to withdraw consent and they were unable to be contacted by the study site. The sites pursued multiple follow-up actions if a participant failed to return to the study site for a required study visit, as detailed in mRNA-1273-P301 Clinical Study Protocol Section 7.4 (Appendix 16.1.1).

3.5.3.2 Participant Withdrawal From Study Treatment

Every reasonable attempt was made to follow up with participants for safety throughout the entire study period, even if further IP injection was withheld or the participant missed 1 or more visits. Unless consent was withdrawn, a participant who withdrew or was withheld from receiving the second dose of IP remained in the study and completed all scheduled visits and assessments. Events that constituted contraindications to administration of IP at certain points in time are summarized in Section 3.6.1.1.

The possible reasons for withdrawal from further injection were identical to those listed in Section 3.5.3.1 for withdrawal from the study.

3.6 Study Treatment

3.6.1 Investigational Product Administered

In Part A, approximately 30,000 participants were randomly assigned in a 1:1 ratio to receive either mRNA-1273 100 µg or placebo (0.9% sodium chloride [normal saline] for injection).

Investigational product (mRNA-1273 100 µg or placebo) was administered as a 0.5 mL IM injection into the deltoid muscle (preferably the nondominant arm) on a 2-dose injection schedule (Day 1 and Day 29). The second dose of IP should have been administered in the same arm as the first dose.

At each visit when IP was administered, participants were monitored for a minimum of 30 minutes after administration. Assessments performed included vital sign measurements and monitoring for local or systemic reactions, as specified in the SoE for the Vaccination Phase, Day 1 through Day 57 (mRNA-1273-P301 Clinical Study Protocol Table 16; Appendix 16.1.1).

Eligibility for subsequent IP injection was determined per the criteria outlined in Section 3.6.1.1.

3.6.1.1 Contraindications to Subsequent Injection and Criteria for Delay of Study Treatment

Prior to receiving a second dose of IP, participants were reassessed to ensure that they continued to meet eligibility requirements as outlined below.

The following events in a participant constituted absolute contraindications to any further injection of the IP to that participant. If any of these events occurred during the study, the participant should not have received additional doses of vaccine but was encouraged to continue study participation for safety through 24 months following last injection.

- (Part A Only) Diagnosed COVID-19 by detection of SARS-CoV-2 in Day 1 NP swab or COVID-19 diagnosed prior to Day 29. If COVID-19 was suspected on or prior to Day 29, further administration of IP was withheld until COVID-19 test results were available.
- Anaphylaxis or systemic hypersensitivity reaction following the administration of vaccine.
- Any SAE judged by investigator or Sponsor to be related to study vaccine.
- Any clinically significant medical condition that, in the opinion of the investigator, posed an additional risk to the participant if he or she continued to participate in the study.

The following events constituted criteria for delay of study vaccination, and if either of these events occurred at the time scheduled for administration of IP, the participant could have been injected at a later date within the time window specified in the SoE for the Vaccination Phase, Day 1 through Day 57 (mRNA-1273-P301 Clinical Study Protocol Table 16; Appendix 16.1.1), or the participant could have been discontinued from IP injection at the discretion of the investigator (Section 3.5.3):

- Acute moderate or severe infection with or without fever at the time of injection
- Fever, defined as body temperature ≥ 38.0°C (100.4°F) at the time of injection

Participants with a minor illness without fever, as assessed by the investigator, could have been administered IP. Participants with a fever of 38.0°C (100.4°F) or higher were contacted within the time window acceptable for participation and re-evaluated for eligibility. If the investigator determined that the participant's health on the day of administration temporarily precluded injection with IP, the visit was rescheduled within the allowed interval for that visit.

3.6.2 Identity of Investigational Products

The term "investigational product" refers to both mRNA-1273 vaccine and placebo administered in this study (Table 3-2). The Sponsor supplied mRNA-1273 and PPD supplied placebo to the sites.

Table 3-2: Investigational Products – Part A

Investigational Product	mRNA Concentration	Dosage Form	Packaging	Lot Numbers
mRNA-1273 vaccine	0.2 mg/mL	Sterile liquid for injection	One labeled carton, containing 1 labeled multidose vial (fill volume 5 mL)	Refer to Appendix 16.1.6
Placebo (0.9% sodium chloride injection, USP)	NA	0.9% sodium chloride (normal saline) solution for injection, USP	1 box, containing 25 single-use vials (10 mL each)	NA

Abbreviations: NA = not applicable; USP = United States Pharmacopeia.

The mRNA-1273 vaccine is an LNP dispersion of an mRNA encoding the prefusion stabilized S protein of SARS-CoV-2 combined in LNPs composed of 4 lipids (1 proprietary and 3 commercially available): the proprietary ionizable lipid SM-102; cholesterol; DSPC; and PEG2000-DMG. The mRNA-1273 vaccine was provided as a sterile liquid for injection and was a white to off white dispersion in appearance, at a concentration of 0.2 mg/mL in 20 mM Tris buffer containing 87 mg/mL sucrose and 10.7 mM sodium acetate at pH 7.5.

The placebo was 0.9% sodium chloride (normal saline) injection, which met the criteria of the United States Pharmacopeia (USP).

Unblinded study site personnel, who did not participate in any other aspect of the study during Part A, performed IP accountability procedures, dose preparation, and IP administration (Section 3.6.4). Unblinded study site personnel used a centralized IRT to manage, track, order, and resupply mRNA-1273 and placebo for the study.

mRNA-1273 was packaged and labeled in accordance with the standard operating procedures (SOPs) of the Sponsor or of its designee, CFR Title 21, Good Manufacturing Practice guidelines, ICH GCP guidelines, guidelines for Quality System Regulations, and applicable regulations.

The 0.9% sodium chloride injection, which was used as both a placebo and a diluent to mRNA-1273, had a commercial label and did not contain study-specific identification.

mRNA-1273 vaccine for Part A was stored at 2°C to 8°C in a secure area with limited access (unblinded study site personnel only) and protected from moisture and light until it was prepared for administration. Details for mRNA-1273 vaccine storage and handling requirements are detailed in mRNA-1273-P301 Clinical Study Protocol Section 6.2.5 (Appendix 16.1.1).

The 0.9% sodium chloride injection (USP) was stored at 20ºC to 25ºC (68ºF to 77ºF) in a restricted access area.

Further description of the IP and instructions for the receipt, storage, preparation, administration, accountability, and destruction of the IP were described in the mRNA-1273-P301 Pharmacy Manual.

3.6.3 Method of Assigning Participants to Treatment Groups

In Part A, after eligibility was confirmed on Day 1, participants were randomly assigned in a 1:1 ratio to receive mRNA-1273 or placebo in a blinded manner using a centralized IRT, in accordance with pre-generated randomization schedules.

Participants were stratified by age (≥ 18 and < 65 years; or ≥ 65 years) and, if participants were < 65 years of age, on the presence or absence of risk factors for severe illness from COVID-19 based on CDC recommendation as of March 2020 (CDC 2020a). The following were the 3 strata for randomization:

- ≥ 18 and < 65 years and not at risk
- ≥ 18 and < 65 years and at risk
- ≥ 65 years

At least 25% of enrolled participants, but not exceeding 50%, were from the ≥ 65 years age group and < 65 years and at risk group.

Participants who were < 65 years old were categorized as at risk for severe COVID-19 illness if they had at least 1 of the following risk factors at Screening:

- Chronic lung disease (eg, emphysema and chronic bronchitis), idiopathic pulmonary fibrosis and cystic fibrosis), or moderate to severe asthma
- Significant cardiac disease (eg, heart failure, coronary artery disease, congenital heart disease, cardiomyopathies, and pulmonary hypertension)
- Severe obesity (body mass index [BMI] ≥ 40 kg/m^2)
- Diabetes (type 1, type 2, or gestational)
- Liver disease
- HIV infection

In Part A, only the unblinded study site personnel (Section 3.6.4) had controlled access to which arm the participant was randomly assigned. Access to the randomization code was strictly controlled at the pharmacy. The randomization schedule was provided to the IA review team after the database was locked for IA (Appendix 16.1.7).

3.6.4 Blinding and Unblinding

In Part A, the randomized, placebo-controlled, blinded phase of this study was observer-blind. The investigator, study staff, study participants, site monitors, and Sponsor personnel (or its designees) were to remain blinded to the IP administered until study end, with the following exceptions:

- Unblinded personnel (of limited number) were to be assigned to vaccine accountability procedures and were to prepare IP for all participants. These personnel were to have no study functions other than study vaccine management, documentation, accountability, preparation, and administration. They were not to be involved in participant evaluations and were not to reveal the identity of IP to either the participant or the blinded study site personnel involved in the conduct of the study unless the information was necessary in the case of an emergency.
- Unblinded medically qualified study site personnel were to administer the IP. They were not to be involved in assessments of any study endpoints.
- Unblinded site monitors, not involved in other aspects of monitoring, were to be assigned as the IP accountability monitors. They were to have responsibilities to ensure that sites were following all proper IP accountability, preparation, and administration procedures.
- The dosing assignment was to be concealed by having the unblinded personnel prepare the IP in a secure location that was not accessible or visible to other study staff. An opaque sleeve over the syringe used for injection maintained the blind at the time of injection, as the doses containing mRNA-1273 looked different than placebo. Only delegated unblinded site staff conducted the injection procedure. Once the injection was completed, only the blinded study staff were to perform further assessments and interact with the participants. Access to the randomization code was strictly controlled at the pharmacy.
- An unblinded statistical and programming team performed the pre-planned IAs.
- The unblinded medical monitor supported writing documents and communications with DSMB with oversight by the unblinded Sponsor clinical representative.
- An independent DSMB reviewed the interim data to safeguard the interests of clinical study participants and to help ensure the integrity of the study. The DSMB reviewed unblinded statistical outputs and IA results, provided by the independent unblinded statistician, and made recommendations to the Sponsor.

- At the initiation of Part B, the Open-Label Observational Phase of this study, site personnel who were blinded during Part A, the randomized, placebo-controlled, blinded phase, were unblinded at the participant level at the PDV.

A participant or participants may have been unblinded in the event of an SAE or other severe event, or if there was a medical emergency requiring the identity of the product to be known to properly treat a participant. If a participant became seriously ill or pregnant during the study, the study investigator may have requested that the blind be broken if knowledge of the administered vaccine affected that participant's dosing options. In this situation or in the event of a medical emergency requiring identification of the IP administered to an individual participant, the investigator made every attempt to contact the Sponsor medical lead to explain the need for opening the code within 24 hours of opening the code. The investigator was responsible for documenting the time, date, reason for the code break, and the names of the study site personnel involved.

In December 2020, COVID-19 vaccines started to become available under EUA as an alternative option to some participants based on evolving recommended populations by the CDC and local supply chain distribution. While all participants were encouraged to stay blinded in the study for as long as possible, their participation did not deny them the opportunity to receive a COVID-19 vaccine under EUA. Prior to implementation of Protocol Amendment 6 (23 Dec 2020; Section 3.2.1), clinical investigators could exercise discretion as to whether individual participants should have been unblinded upon request to allow them to make an informed decision regarding receipt of a COVID-19 vaccine outside of this study. Investigator judgment considered a participant's risk status under CDC recommendations, any current local public health guidance, and their access to imminently receive a COVID-19 vaccine under an EUA. Participants who were unblinded prior to Protocol Amendment 6 and determined to have received placebo, were discontinued from the study by the investigator to permit given the intention of the participant to receive vaccine under EUA. Those who received mRNA-1273 were encouraged to continue participation in an open-label manner unless the participant withdrew informed consent.

Participants who were confirmed to have received placebo upon unblinding and intended to receive a COVID-19 vaccine under an EUA outside of this study were to be withdrawn from the study at the point of unblinding.

Note: Participants who requested unblinding because of a stated imminent access to a COVID-19 vaccine under an EUA outside of this study, were withdrawn from study, and then were unable to in fact receive a COVID-19 vaccine, were permitted to re-enter the study upon reconsent to receive the mRNA-1273 vaccine once they were EUA eligible.

3.6.5 Treatment Compliance

All doses of IP were administered at the study site under direct observation of unblinded medically qualified study site personnel and appropriately recorded (date and time) in the eCRF. Unblinded study site personnel confirmed that the participant received the entire dose of vaccine or placebo. If a participant did not receive vaccine or placebo or did not receive all of the planned number of doses, the reason for the missed dose was recorded. Data were reconciled with site accountability records to assess compliance.

The required process was followed even if participants missed the second dose of IP due to noncompliance with the visit schedule and not due to a safety pause and for ensuring participants complied with the allowed study windows, as described in mRNA-1273-P301 Clinical Study Protocol Section 6.3 (Appendix 16.1.1).

3.6.6 Prior and Concomitant Medications and Therapies

3.6.6.1 Prior Medications and Therapies

A prior medication was defined as a medication received before first IP administration. Information about prior medications (including any prescription or over-the-counter medications, vaccines, or blood products) taken by the participant within the 28 days before providing informed consent (or as designated in the inclusion/exclusion requirements) were recorded in the participant's eCRF.

3.6.6.2 Concomitant Medications and Therapies

A concomitant medication was defined as a medication that continued or was newly received at or after the first injection through 28 days after the last injection. A post medication was defined as a medication received more than 28 days after the last injection. At each study visit, study site personnel questioned the participant regarding any medications taken and non-study vaccinations the participant received and recorded the information in the eCRF.

In Part A only, participants were asked in the eDiary if they had taken any antipyretic or analgesic to treat or prevent fever or pain within 7 days after each IP injection, including the day of administration. Reported antipyretic or analgesic medications were recorded in the source document by the site staff during the post-injection study visits or via other participant interactions (eg, telephone calls).

The information recorded for concomitant medications, non-study vaccination, and treatment medication is described in mRNA-1273-P301 Clinical Study Protocol Section 6.4.2 (Appendix 16.1.1).

Concomitant medications and/or vaccines that did not require withdrawal of the participant from the study but may have impacted a participant's eligibility to receive a second dose or evaluability in the per-protocol (PP) analysis are listed in mRNA-1273-P301 Clinical Study Protocol Section 6.4.3 (Appendix 16.1.1). Contraindications for administration of the second dose are provided in Section 3.6.1.1.

If a participant took a drug therapy that was prohibited by the protocol, the investigator and PPD's medical monitor made a joint decision about continuing or withholding further administration of IP to the participant based on the time the medication was administered, the drug's pharmacology and pharmacokinetics, and whether use of the medication compromised the participant's safety or interpretation of the data. It was the investigator's responsibility to ensure that details regarding concomitant medications were adequately recorded in the eCRF.

All medication and interventions necessary for the appropriate care for the study participant, particularly to treat COVID-19, were administered and appropriately documented along with the AE.

3.7 Efficacy, Safety, and Immunogenicity Measurements Assessed and Schedule of Assessments

3.7.1 Study Assessments and Schedule of Events

The SoEs for all participants are presented in mRNA-1273-P301 Clinical Study Protocol Table 16 (Vaccination Phase, Day 1 - Day 57), Table 17 (Surveillance Phase, Day 64 - Day 394), Table 18 (Surveillance Phase, Day 401 - Day 759), Table 19 (Convalescent Period, Starting with the Illness Visit), and Table 20 (Part B: Participant Decision Clinic Visit) (Appendix 16.1.1).

Participants eligible for Part B open-label IP injection may have up to 3 additional scheduled clinic visits (Section 3.1.2) as specified in the mRNA-1273-P301 Clinical Study Protocol Table 21 (Supplemental Schedule of Events: Open-Label Observational Phase - Placebo Participants who request to receive mRNA-1273) and Table 22 (Modified Supplemental Schedule of Events: Open-Label Observational Phase – mRNA-1273 Participants who ONLY received 1 dose of mRNA-1273) (Appendix 16.1.1).

A participant also could have had an unscheduled visit at any time during the study. An unscheduled visit could have been prompted by Illness Visit criteria for COVID-19 or new or ongoing AEs (including vaccine reactogenicity). The site also had the discretion to make reminder telephone calls or send text messages to inform the participant about visits, review eDiary requirements, or follow up on ongoing or outstanding issues. These reminders were in addition to the protocol-specified visits.

In accordance with the FDA Guidance on Conduct of Clinical Trials of Medical Products During the COVID-19 Public Health Emergency (DHHS 2020a), investigators could have converted study site visits to telemedicine visits with the approval of the Sponsor. Such action was taken to protect the safety and well-being of study participants and study site personnel or to comply with state or municipal mandates.

3.7.1.1 Use of Electronic Diary

In Part A, the randomized, placebo-controlled, blinded phase of the study, before enrollment on Day 1, participants were instructed to download the eDiary application on their personal smartphone or were provided a Sponsor-provisioned device to record solicited ARs; the eDiary also provided prompts to elicit an unscheduled Illness Visit if the participant experienced COVID-19 symptoms (Section 3.7.2.1).

In Part A, the randomized, placebo-controlled, blinded phase of the study, at each injection visit, participants recorded data into the eDiary starting approximately 30 minutes after injection under supervision of the study site personnel to ensure successful entry of assessments. The 30-minute assessment was an opportunity for study site personnel to train the participant. The study site personnel performed any retraining as necessary. Study participants continued to record data in an eDiary after they left the study site, preferably in the evening and at the same time each day, on the day of injection and for 6 days following injection. If on Day 7 an AR persisted, the eDiary prompts and entries were continued until resolution.

In Part A, the randomized, placebo-controlled, blinded phase of the study, solicited local and systemic reactogenicity ARs, as defined in Section 3.7.4.1, were collected on the day of each IP injection, during the 7 days after IP injection (ie, the day of injection and 6 subsequent days; or until resolution for solicited ARs that continued beyond 7 days), and weekly thereafter. Any solicited AR that was ongoing beyond Day 7 was reported in an eDiary until resolution. Adverse reactions recorded in diaries beyond Day 7 were reviewed by study site personnel either during the next scheduled telephone call or at the next study site visit.

After Study Day 57, the eDiary prompted each participant weekly to surveil for potential symptoms of COVID-19. If eDiary prompts resulted in identification of relevant safety events according to the study period or symptoms of COVID-19, a follow-up safety call was triggered.

In Part A, the randomized, placebo-controlled, blinded phase of the study, at each injection visit, participants were instructed or reminded on thermometer usage to measure body temperature, ruler usage to measure injection site erythema and swelling/induration (hardness), and self-assessment for localized axillary swelling or tenderness on the same side as the injection arm.

In Part A, the randomized, placebo-controlled, blinded phase of the study, daily oral body temperature measurement was performed at approximately the same time each day using the thermometer provided by the study site.

Surveillance for signs and symptoms of COVID-19 started at Day 1 and are continuing through the entire Surveillance Phase (Day 64 to Month 25). After participants completed Part A, the weekly eDiary Safety Follow-Up Prompts were to be triggered on Day 61. Each week (ie, every 7 days) the participant received a prompt on their smartphone device to regularly surveil for signs and symptoms of COVID-19. The participant was trained on how to complete the weekly eDiary prompts at the Day 57 clinic visit and was also reminded to call the site immediately if they experienced any COVID-19 symptoms. The weekly eDiary prompt inquired about the following:

- Changes in health since the last time completing the weekly eDiary prompt or the last contact with the study site personnel
- Any known exposure to someone with SARS-CoV-2 infection or COVID-19 since the last time completing the weekly eDiary prompt or the last contact with the study site personnel
- Capture of any COVID-19 symptoms currently being experienced or experienced since the last time completing the weekly check-in as defined in Section 3.7.2.1
- Any contact with a healthcare provider that may indicate an MAAE

A positive response by the participant to these prompts resulted in a notification to both the participant and study site personnel to arrange a call. A follow-up safety call was performed to determine if an unscheduled Illness Visit for the participant was needed (defined in Section 3.7.2.2). The results of the safety call were recorded in the appropriate source documentation.

If a participant did not respond to the weekly eDiary within a 2-day window around the scheduled time point, study site personnel followed up directly with the participant via telephone call or text to confirm their health status and to remind the participant of the importance of maintaining weekly contact via the eDiary prompt.

In addition, an eDiary prompt was implemented to solicit the collection of information regarding participant's history of facial injections or dermal fillers, for cosmetic or medical indications such as migraine headaches.

3.7.1.2 Safety Telephone Call

A safety telephone call was a telephone call made to the participant by medically qualified study site personnel. Medically qualified study site personnel were those appropriately delegated individuals who were permitted to elicit verbal medical history from participants based on local regulations and local licensing requirements.

The call followed a script, which facilitated the collection of relevant safety information. The participant was interviewed according to the script about occurrence of unsolicited AEs, MAAEs, SAEs, AEs leading to study withdrawal and concomitant medications associated with those events, receipt of any non-study vaccinations, and pregnancy.

The timing of the safety telephone calls and the relevant safety information collected were indicated in the SoEs (mRNA-1273-P301 Clinical Study Protocol Section 11.1; Appendix 16.1.1).

All safety information collected from the telephone contact was documented in source documents as described by the participant and not documented on the script used for the safety telephone contact. All AEs, MAAEs, SAEs, and AEs leading to study withdrawal were recorded in the eCRF as specified in Section 3.7.4.2.

3.7.2 Efficacy Assessments

The primary and secondary efficacy endpoints are provided in Section 2.

The efficacy in this study was determined based on defined cases of COVID-19. Cases were defined as participants meeting clinical criteria based both on symptoms for COVID-19 (Section 3.7.2.1) and on RT-PCR detection of SARS-CoV-2 (Section 3.7.2.3) from samples collected within 72 hours of the study participant reporting symptoms that met the definition of COVID-19. Participants who were hospitalized for COVID-19 without the opportunity for a clinic or home visit were also considered cases, assuming that the symptomology criteria for COVID-19 were met and a respiratory sample was positive for SARS-CoV-2 by RT-PCR at a Clinical Laboratory Improvement Amendments (CLIA)-certified laboratory. Investigators were encouraged to obtain a respiratory sample during the course of hospitalization for submission to the study central laboratory, if feasible. The investigator was required to determine if the criteria for severe COVID-19 had been met. The surveillance for COVID-19 symptoms, including signs of severe systemic illness and the corresponding clinical pathways for data collection, is presented graphically in mRNA-1273-P301 Clinical Study Protocol Figure 4 (Appendix 16.1.1).

An AC, blinded to treatment assignment, reviewed potential cases (Section 3.8.4.3).

Definitions of severe COVID-19, secondary cases of COVID-19, and death attributed to COVID-19 are included in the respective defined secondary efficacy endpoints (Section 2).

3.7.2.1 Surveillance for COVID-19 Symptoms

Surveillance for COVID-19 symptoms was conducted via weekly telephone calls in Part A, Blinded Phase and Part B, Open-Label Observational Phase of the study and/or eDiary prompts as specified in Section 3.7.1.1, starting after enrollment and throughout the study. If there was no response to an eDiary prompt for 2 days, the study site personnel contacted the study participant by telephone.

According to the CDC as of 10 Jun 2020 (CDC 2020b), patients with COVID-19 have reported a wide range of symptoms ranging from mild symptoms to severe illness. Throughout the study, to surveil for COVID-19, the following prespecified symptoms that met the criteria for suspicion of COVID-19 were elicited weekly from the participant, and the presence of any one of these symptoms lasting at least 48 hours (except for fever and/or respiratory symptoms) resulted in the site arranging an Illness Visit to collect an NP swab within 72 hours:

- Fever (temperature ≥ 38ºC) or chills (of any duration, including ≤ 48 hours)
- Shortness of breath or difficulty breathing (of any duration, including ≤ 48 hours)
- Cough (of any duration, including ≤ 48 hours)
- Fatigue
- Muscle or body aches
- Headache
- New loss of taste or smell
- Sore throat
- Congestion or runny nose
- Nausea or vomiting
- Diarrhea

Importantly, some of the symptoms of COVID-19 overlap with solicited systemic ARs that are expected after vaccination with mRNA-1273 (eg, myalgia, headache, fever, and chills). During the first 7 days after IP injection, when these solicited ARs might be common, investigators used their clinical judgment and decided if an NP swab should be collected. The collection of an NP swab prior to the Day 1 and Day 29 vaccination helped ensure that cases of COVID-19 were not

overlooked. Any study participant reporting respiratory symptoms during the 7-day period after vaccination was evaluated for COVID-19.

During the course of the study, participants with symptoms of COVID-19 were asked to return within 72 hours or as soon as possible to the study site, or medically qualified study site personnel from the study site conducted a home visit as soon as possible to collect an NP swab sample (for RT-PCR), collect a blood sample for immunologic analysis of SARS-CoV-2 infection, and to evaluate for COVID-19. Both study site visits and home visits were referred to as Illness Visits (Section 3.7.2.2). The NP swab sample was also tested for the presence of other respiratory infections.

All clinical findings were recorded in the eCRF. All confirmed cases of COVID-19 were to be captured as MAAEs, along with relevant concomitant medications and details about severity, seriousness, and outcome.

3.7.2.2 Assessments During Convalescence Period, Starting at Illness Visit

All study participants who experienced COVID-19 symptoms and subsequently presented for an Illness Visit (in clinic or at home) were given an instruction card listing symptoms and severity grading system, a thermometer, an oxygen saturation monitor, and saliva collection tubes. Participants were trained on the use of the oxygen saturation monitor and how to take saliva specimens. The list of symptoms is provided in Section 3.7.2.1 and the severity scoring system is presented in mRNA-1273-P301 Clinical Study Protocol Table 3 (Appendix 16.1.1).

A study site Illness Visit may have included assessments such as medical history, physical examination, blood sampling for clinical laboratory testing, and NP swab sampling for viral PCR (including multiplex PCR for respiratory viruses including SARS-CoV-2) to evaluate the severity of the clinical case. Radiologic imaging studies may have been conducted. Blood samples were collected for potential future immunologic assessment of SARS-CoV-2 infection.

The initial Illness Visit was considered Day 1 for the Convalescent Period. Starting on Day 2 of the Convalescent Period, the investigator (or medically qualified study site personnel appropriately delegated by the investigator) contacted participants daily with telemedicine visits through Day 14 or until symptoms resolved, whichever was later. Telemedicine visits (videoconference or audio only) included participant-reported symptoms, severity of symptoms, body temperature, and oxygen saturation, as detailed in mRNA-1273-P301 Clinical Study Protocol Section 8.1.3 and Table 19 (Appendix 16.1.1). Participants were also reminded to collect their saliva sample 3, 5, 7, 9, 14, and 21 days after the initial Illness Visit and to return the sample to the study site. Immediately upon receipt of a saliva sample, the study site sent it for testing to the study central virology laboratory.

If the participant had a positive result for SARS-CoV-2 from the Day 1 Illness Visit, the participant continued the Convalescent Period; if the result was negative, the participant exited the Convalescent Period, including discontinuation of daily telemedicine visits and collection of saliva samples, and followed the respective SoE (mRNA-1273-P301 Clinical Study Protocol Table 16, Table 17, and Table 18; Appendix 16.1.1)

All participants confirmed with COVID-19 cases were scheduled for a Convalescent Visit (study site or home visit) 28 days after the initial Illness Visit. At this visit, a saliva (or nasal swab) sample was collected, and a blood sample was drawn for immunologic assessment of SARS-CoV-2 infection.

If the participant was hospitalized, medically qualified study site personnel tried to obtain medical records and SARS-CoV-2 diagnostic results and document if the criteria for COVID-19 or severe COVID-19 had been met. If the participant was later discharged from the hospital during the 28-day period following diagnosis of COVID-19, the study site personnel arranged for a resumption of a schedule for telemedicine visits and sampling for the remainder of the Convalescent Period, followed by a return to their respective study schedule.

3.7.2.3 Testing for SARS-CoV-2 Infection

3.7.2.3.1 Reverse Transcriptase-Polymerase Chain Reaction in Nasopharyngeal and Nasal Swabs Samples

Nasopharyngeal swab sample were collected for SARS-CoV-2 on Day 1 and Day 29, prior to receiving a dose of the IP, and at the PDV as specified in mRNA-1273-P301 Clinical Study Protocol Table 16 and Table 20 (Appendix 16.1.1). If COVID-19 symptoms reported lasted at least 48 hours (except for fever and/or respiratory symptoms), an Illness Visit was scheduled to collect an NP swab or nasal swab samples were obtained (Section 3.7.2.2).

Nasopharyngeal specimens collected from individuals with symptoms of COVID-19 were tested for SARS-CoV-2 infection using SARS-CoV-2 specific RT-PCR in support of primary and secondary study endpoints. Summary of RT-PCR (upper respiratory samples) method and method validation parameters (eg, sensitivity, specificity, reliability, validity) for this bioassay are presented in Appendix 16.6.

3.7.2.3.2 Elecsys Anti-SARS-CoV-2 Immunoassay in Serum and plasma samples

Elecsys Anti-SARS-CoV-2 immunoassay was used for the qualitative detection of bAb to SARS-CoV-2 N antigen in human serum and plasma. The Elecsys anti-SARS-CoV-2 aided in

identifying individuals with an adaptive immune response to SARS-CoV-2 at the time of enrollment and at subsequent time points in support of primary and secondary study endpoints.

Blood samples for immunologic assessment of SARS-CoV-2 infection were collected according to time points indicated in the SoEs (mRNA-1273-P301 Clinical Study Protocol Section 11.1 [Appendix 16.1.1]).

Summary of Elecsys Anti-SARS-CoV-2 immunoassay (ELECSYS: N-protein IgG) method and method validation parameters (eg, sensitivity, specificity, reliability, validity) for this bioassay are presented in Appendix 16.6.

3.7.2.3.3 Genotypic Analysis of SARS-CoV-2 Variants

Evaluation of genotypic/phenotypic relationship of isolated SARS-CoV-2 strains was performed using residue specimens initially collected for the qualitative detection of RNA from SARS-CoV-2 from nasal swabs (Section 3.7.2.3.1). No additional samples were collected for this analysis.

Two genotypic analysis were performed in support of exploratory endpoints:

- NGS RT-PCR based assay sequencing the whole SARS-CoV-2 S-protein genome.
- WGS RT-PCR based assay sequencing the whole SARS-CoV-2 genome.

Summary of both these sequencing methods (RT-PCR NGS and RT-PCR WGS) and method validation parameters (eg, sensitivity, specificity, reliability, validity) for both bioassays are presented in Appendix 16.6.

3.7.2.3.4 Viral Load Analysis of SARS-CoV-2 in Saliva Samples

Participants with a positive RT-PCR (NP-swabs) (Section 3.7.2.3.1) result for SARS-CoV-2 from the Day 1 Illness Visit, collected their own saliva samples (respiratory illness sample) during the telemedicine visits convalescent period on 3, 5, 7, 9, 14, and 21 days after the initial Illness Visit (mRNA-1273-P301 Clinical Study Protocol Section 11.1 [Appendix 16.1.1]).

These saliva specimens were analyzed using a SARS-CoV-2 specific RT-qPCR assay intended for quantitative detection of RNA from SARS-CoV-2 virus to analyze SARS-CoV-2 viral load over time after infection in support of exploratory endpoints.

Summary of this method (RT-qPCR [saliva sample]) and method validation parameters (eg, sensitivity, specificity, reliability, validity) are presented in Appendix 16.6.

3.7.3 Immunogenicity Assessments

The secondary and exploratory immunogenicity endpoints are provided in Section 2. Blood samples for immunogenicity assessments continue as planned at the time points indicated in the SoEs (mRNA-1273-P301 Clinical Study Protocol Section 11.1 [Appendix 16.1.1]).

In Part A, on Day 1 and Day 29, blood samples for immunogenicity assessment were collected before administration of IP. The following antigens were measured:

- Serum bAb levels against SARS-CoV-2 as measured by ligand-binding assay specific to the SARS-CoV-2 S-2P-protein (ELISA).
- Serum bAb levels against SARS-CoV-2 as measured by ligand-binding assay specific to the SARS-CoV-2 S protein (MSD).
- Serum nAb titer against SARS-CoV-2 as measured by pseudovirus neutralization assays (PsVNA).

The actual time and date of each sample collected was recorded in the eCRF, and unique sample identification was used to maintain the blind at the laboratory at all times and allowed for automated sample tracking and storage. Handling and preparation of the samples for analysis, as well as shipping and storage requirements, were described in a separate study manual.

These assays were performed in laboratories designated by the Sponsor (Section 3.3). Summaries of S-protein bAb (ELISA: S-2P protein IgG and MSD Multiples: S-protein IgG) and nAb (PsVNA) assay methodologies and method validation parameters (eg, sensitivity, specificity, reliability, validity) for each bioassay are presented in Appendix 16.6.

3.7.4 Safety Assessments

Safety assessments included monitoring and recording of the following for each participant:

- Solicited local and systemic ARs (Section 3.7.4.1) that occur during the 7 days following each injection (ie, the day of injection and 6 subsequent days; or until resolution for solicited ARs that continued beyond 7 days). Solicited ARs will be recorded daily using eDiaries (Section 3.7.1.1).
- Unsolicited AEs observed or reported during the 28 days following each dose of IP (ie, the day of injection and 27 subsequent days). Unsolicited AEs are AEs that are not included in the protocol-defined solicited ARs.
- AEs leading to discontinuation from injection and/or study participation from Day 1 through Day 759 or withdrawal from the study.

- MAAEs from Day 1 through Day 759 or withdrawal from the study.
- SAEs from Day 1 through Day 759 or withdrawal from the study.
- Abnormal vital sign measurements.
- Physical examination findings.
- Pregnancy and accompanying outcomes.
- Concomitant medications and non-study vaccinations.

3.7.4.1 Solicited Adverse Reactions (Part A, Blinded Phase Only)

The term "reactogenicity" referred to the occurrence and intensity of selected signs and symptoms (ARs) occurring after IP injection. The eDiary solicited daily participant reporting of ARs using a structured checklist. Participants recorded such occurrences in an eDiary on the day of each IP injection and for 6 subsequent days (or until resolution for solicited ARs that continued beyond 7 days).

Severity grading of reactogenicity occurred automatically based on participant entry into the eDiary according to the grading scales presented in mRNA-1273-P301 Clinical Study Protocol Table 5 (Appendix 16.1.1) modified from the Toxicity Grading Scale for Healthy Adult and Adolescent Volunteers Enrolled in Preventative Vaccine Clinical Trials (DHHS 2007).

If a solicited local or systemic AR continued beyond 7 days after injection, the participant was prompted daily to capture the solicited local or systemic AR in the eDiary until resolution. Adverse reactions recorded in eDiaries beyond Day 7 were reviewed by the investigator either via telephone call or at the following study visit. All solicited ARs (local and systemic) were considered causally related to IP injection.

Any solicited AR that met any of the following criteria was entered into the participant's source document and also recorded as an AE in the participant's Adverse Event eCRF:

- Solicited local or systemic AR that resulted in a visit to a healthcare practitioner (HCP) (MAAE)
- Solicited local or systemic AR that led to the participant withdrawing from the study or the participant being withdrawn from the study by the investigator (AE leading to withdrawal)
- Solicited local or systemic AR that lasted beyond 7 days post injection
- Solicited local or systemic AR that led to participant withdrawal from IP

- Solicited local or systemic AR that otherwise met the definition of an SAE

3.7.4.2 Adverse Events, Serious Adverse Events, and Medically Attended Adverse Events

The investigator was responsible for reporting all AEs that were observed or reported during the study, regardless of their relationship to vaccine or their clinical significance. If there was any doubt as to whether a clinical observation was an AE, the event was reported.

The AE and SAE definitions are provided in the mRNA-1273-P301 Clinical Study Protocol Section 8.3.1 and Section 8.3.3 (Appendix 16.1.1). A TEAE was defined as any event that was not present before exposure to vaccine or any event that was already present which worsened in intensity or frequency after exposure.

An unsolicited AE was any AE reported by the participant that was not specified as a solicited AR in the protocol or was specified as a solicited AR in the protocol but started outside the protocol-defined, post-injection period for reporting solicited ARs (ie, for the 7 days after each injection).

An MAAE was an AE that led to an unscheduled visit (including telemedicine visit) to a HCP. This included visits to a study site for unscheduled assessments (eg, rash assessment, abnormal laboratory follow-up, COVID-19) and visits to HCPs external to the study site (eg, urgent care, primary care physician). Investigators reviewed unsolicited AEs for the occurrence of any MAAEs. All MAAEs were fully reported on the MAAE page of the eCRF.

All suspected cases of anaphylaxis were recorded as MAAEs and reported as an SAE, based on criteria for a medically important event, unless the event met other serious criteria. An AR was any AE for which there was a reasonable possibility that the IP caused the AE. For the purposes of investigational new drug safety reporting, “reasonable possibility” means that there was evidence to suggest a causal relationship between the IP and the AE.

At every study site visit or telephone contact, participants were asked a standard question to elicit any medically related changes, including surveillance for COVID-19 symptoms, in their well-being according to the scripts provided. Participants were also asked if they were hospitalized, had any accidents, used any new medications, changed concomitant medication regimens (both prescription and over-the-counter medications), or had any non-study vaccinations.

In addition to participant observations, physical examination findings or other documents relevant to participant safety classified as an AE were documented on the AE page of the eCRF.

All AEs, SAEs, and MAAEs were reported in detail on the appropriate page of the eCRF and followed until resolution, stabilization, the event was otherwise explained, or the participant was lost to follow-up.

The following information on AEs was obtained:

- Type: MAAE, solicited AR
- Seriousness
- Duration (start and stop dates)
- Severity: mild, moderate, or severe
- Relationship to IP: not related, related, not applicable (if event occurred before first dose)
- Relationship to study procedure: not related, related, not applicable (if event occurred before first dose)
- Actions taken
- Outcome

Additional information on reporting and documenting AEs and SAEs as well as assessment of causality and severity are provided in the mRNA-1273-P301 Clinical Study Protocol Section 8.3 (Appendix 16.1.1).

3.7.4.3 Vital Sign Measurements

Vital signs were measured at the time points indicated in the SoEs (mRNA-1273-P301 Clinical Study Protocol Section 11.1 [Appendix 16.1.1]). The participant was seated for at least 5 minutes before all measurements were taken. On Day 1 and Day 29, vital sign measurements were collected once before IP injection and at least 30 minutes after IP injection (before participants were discharged from the study site). When applicable, vital sign measurements were performed before blood collection.

Febrile participants at Day 1 and Day 29 visits (fever defined as a body temperature ≥ 38.0°C/100.4°F) were rescheduled within the relevant window periods. Afebrile participants with minor illnesses could have received their assigned IP at the discretion of the investigator.

If any of the vital sign measurements met the toxicity grading criteria for clinical abnormalities of Grade 3 (severe) or greater, the abnormal value and grade were documented on the AE page of the eCRF (unless there was another known cause of the abnormality that resulted in an AE classification). The investigator continued to monitor the participant with additional assessments until the vital sign value reached the reference range, returned to the vital sign value at baseline,

was considered stable, or until the investigator determined that follow-up was no longer medically necessary.

3.7.4.4 Physical Examinations

A full physical examination, including vital signs, height, and weight, was performed at Screening and on Day 1, and symptom-directed physical examinations at other scheduled time points as indicated in the SoEs (mRNA-1273-P301 Clinical Study Protocol Section 11.1 [Appendix 16.1.1]). The full examination included assessment of skin, head, ears, eyes, nose, throat, neck, thyroid, lungs, heart, cardiovascular, abdomen, lymph nodes, and musculoskeletal system/extremities. Symptom-directed physical examinations may have been performed at other time points at the discretion of the investigator.

On each dosing day before injection, the arm receiving the injection was examined and the associated lymph nodes were evaluated.

Body mass index was calculated at the Screening Visit (Day 0).

Any clinically significant finding identified during a study visit after the first dose was reported as an MAAE.

Significant new findings that began or worsened after informed consent were recorded on the AE eCRF page.

3.7.5 Other Assessments

3.7.5.1 Other Virus/Bacteria Infection Analysis

For the RT-PCR analysis of other (not SARS-CoV-2) viral or bacterial infection, an independent NP swab sample was collected for SARS-CoV-2 on Day 1 Illness Visit and analyzed using BioFire FilmArray® Respiratory Panel (RP) assay.

The BioFire FilmArray® RP is a diagnostic multiplex PCR test performed to simultaneous detecting 20 different viruses and bacteria associated with respiratory tract infection (Adenovirus, Coronavirus 229E/HKU1/NL63/OC4, Human Metapneumovirus, Human Rhinovirus, Influenza A/A-H1/A-H1-2009/A-H3/B, Parainfluenza 1/2/3/4, Respiratory Syncytial Virus, *Bordetella pertussis/parapertussis* and *Chlamydophila/Mycoplasma pneumoniae*).

This qualitative bioassay was performed in support of exploratory endpoints. Summary of BioFire RP (RT-PCR BioFire) method and method validation parameters (eg, sensitivity, specificity, reliability, validity) are presented in Appendix 16.6.

3.7.6 Appropriateness of Measurements

Efficacy measurements used in this study were selected based on discussions with regulatory authorities and were in line with the recommendations set forth in the FDA Guidance on Development and Licensure of Vaccines to Prevent COVID-19 (DHHS 2020c). The primary endpoint was accepted, and on 18 Dec 2020, the US FDA granted EUA for the mRNA-1273 vaccine for the prevention of COVID-19 (DHHS 2021). Diagnostic testing for SARS-CoV-2 infection was performed using validated assays and/or assays authorized by the FDA under EUA (Section 3.7.2.3).

The safety measures included in this study were appropriate for a preventative vaccine for an infectious disease, including assessment of solicited ARs and unsolicited AEs.

The immunogenicity measures (quantification of neutralizing and binding antibodies) used in this study were standard and appropriate and were performed using validated assays (Section 3.7.3).

3.8 Data Quality Assurance

Data collection was the responsibility of the study site personnel at the site under the supervision of the study site investigator. The investigator was responsible for ensuring the accuracy, completeness, legibility, and timeliness of the data reported.

- All participant data relating to the study were recorded in the eCRF unless transmitted to the Sponsor or designee electronically (eg, laboratory data). The investigator was responsible for verifying that data entries were accurate and correct by physically or electronically signing the eCRF.
- The investigators were expected to maintain accurate documentation (source data) that supported the information entered in the eCRF.
- The investigator permitted study-related monitoring, audits, IRB/IEC review, and regulatory agency inspections and provided direct access to source data documents.
- Monitoring details describing strategy (eg, risk-based initiatives in operations and quality such as Risk Management and Mitigation Strategies and Analytical Risk-Based Monitoring), methods, responsibilities and requirements, including handling of noncompliance issues and monitoring techniques (central, remote, or on-site monitoring) were provided in the study Monitoring Plan, Centralized Monitoring Plan, and Risk Management Plan.

- The Sponsor or designee was responsible for the data management of this study including quality checking of the data.
- The Sponsor assumed accountability for actions delegated to other individuals (eg, CROs).
- Study monitors performed ongoing source data verification to confirm that data entered into the CRF by authorized study site personnel were accurate, complete, and verifiable from source documents; that the safety and rights of participants were being protected; and that the study was conducted in accordance with the currently approved protocol and any other study agreements, ICH GCP, and all applicable regulatory requirements.
- Records and documents, including signed ICFs, pertaining to the conduct of this study are required to be retained by the investigator for 15 years after study completion unless local regulations or institutional policies require a longer retention period. No records may be destroyed during the retention period without the written approval of the Sponsor. No records may be transferred to another location or party without written notification to the Sponsor.

Quality assurance (QA) included all the planned and systematic actions that were established to ensure that the clinical study was performed, and the data were generated, documented (recorded), and reported according to ICH GCP and local/regional regulatory standards.

A QA representative from the Sponsor or qualified designee, who was independent of and separated from routine monitoring, periodically arranged inspections/audits of the clinical study by reviewing the data obtained and procedural aspects. These inspections may have included on-site inspections/audits and source data checks. Direct access to source documents was required for the purpose of these periodic inspections/audits.

3.8.1 Data Collection and Management

This study was conducted in compliance with ICH CGP guidelines. This study was also conducted in accordance with the most recent version of the Declaration of Helsinki.

This study used electronic data collection (to collect data directly from the investigational site using eCRFs). The investigator was responsible for ensuring that all sections of each eCRF were completed promptly and correctly and that entries could have been verified against any source data.

Study monitors performed source document verification to identify inconsistencies between the eCRFs and source documents. Discrepancies were resolved in accordance with the principles of GCP. Detailed study monitoring procedures were provided in the clinical monitoring plan.

Adverse events were coded with the most current available version of MedDRA. Concomitant medications were coded using the WHO Drug Reference List.

3.8.2 Study Monitoring

Before an investigational site entered a participant into the study, a representative of the Sponsor or its representatives visited the investigational study site to:

- Determine the adequacy of the facilities.
- Discuss with the investigator(s) and other study site personnel their responsibilities with regard to protocol adherence, and the responsibilities of Moderna or its representatives. This was documented in a Clinical Study Agreement between the Sponsor, designated CRO, and the investigator.

According to ICH GCP guideline, the Sponsor of the study was responsible for ensuring the proper conduct of the study with regard to protocol adherence and validity of data recorded on the eCRFs. The study monitor's duties were to aid the investigator and Moderna in the maintenance of complete, accurate, legible, well-organized, and easily retrievable data. The study monitor advised the investigator of the regulatory necessity for study-related monitoring, audits, IRB/IEC review, and inspection by providing direct access to the source data/documents. In addition, the study monitor explained to and interpreted for the investigator all regulations applicable to the clinical evaluation of an IP as documented in ICH guidelines.

It was the study monitor's responsibility to inspect the eCRFs and source documentation throughout the study to protect the rights of the participants; to verify adherence to the protocol; to verify completeness, accuracy, and consistency of the data; and to confirm adherence of study conduct to any local regulations. Details were outlined in the clinical monitoring plan. During the study, a monitor from Moderna or a representative are planned to have regular contacts with the investigational site, for the following:

- Provide information and support to the investigator(s).
- Confirm that facilities remain acceptable.
- Confirm that the investigational team is adhering to the protocol, that the data are being accurately recorded in the eCRFs, and that IP accountability checks are being performed.
- Perform source data verification. This includes a comparison of the data in the eCRFs with the participant's medical records at the hospital or practice, and other records relevant to the study. This will require direct access to all original records for each participant (eg, clinical charts or electronic medical record system).

- Record and report any protocol deviations not previously sent.
- Confirm AEs and SAEs have been properly documented on eCRFs and confirm any SAEs have been forwarded to the SAE Hotline, and those SAEs that met criteria for reporting have been forwarded to the IRB/IEC.

The monitor was available between visits if the investigator(s) or other study site personnel needed information or advice.

In accordance with the FDA Guidance on Conduct of Clinical Trials of Medical Products During the COVID-19 Public Health Emergency (DHHS 2020d), investigators may have converted study site visits to telemedicine visits with the approval of the Sponsor.

3.8.3 Audits

Moderna, their designee(s), the IRB/IEC, or regulatory authorities were allowed to conduct site visits to the investigational facilities for the purpose of monitoring or inspecting any aspect of the study. The investigator agreed to allow Moderna, their designee(s), the IRB/IEC, or regulatory authorities to inspect the IP storage area, IP stocks, IP records, participant charts and study source documents, and other records relative to study conduct.

Authorized representatives of Moderna, a regulatory authority, and any IRB/IEC could visit any site to perform audits or inspections, including source data verification. The purpose of a Sponsor audit or inspection was to systematically and independently examine all study-related activities and documents to determine whether these activities were conducted, and data were recorded, analyzed, and accurately reported according to the protocol, ICH GCP E6(R2), and any applicable regulatory requirements. The investigator was required to notify Moderna immediately if contacted by a regulatory agency about an inspection.

The principal investigator obtained IRB approval for the investigation. Initial IRB approval and all materials approved by the IRB for this study, including the participant consent form and recruitment materials, were maintained by the investigator and made available for inspection.

3.8.4 Safety Monitoring Committees

3.8.4.1 Protocol Safety Review Team

A PSRT was formed to review interim and cumulative blinded safety data on a regular basis with a remit to escalate concerns to the DSMB. The PSRT was composed of the study's 3 coordinating investigators and representatives from Moderna, NIAID, Biomedical Advanced Research and Development Authority (BARDA), and the CRO. The PSRT composition, its remit, and the routine and systematic procedures for safety review and oversight of blinded

interval and cumulative data during the mRNA-1273 P301 study by the PSRT is documented in the Moderna mRNA-1273 P301 Protocol Safety Review Team Charter.

3.8.4.2 Data and Safety Monitoring Board

An independent DSMB periodically reviewed blinded and unblinded data, including both safety and cases of COVID-19 at scheduled data review meetings and at 2 planned IAs. The DSMB was a multidisciplinary group independent of the study's academic partners, Oversight Group, Sponsor, and United States Government. Members had expertise in biostatistics, clinical trials, infectious diseases, vaccine development, vaccine safety and ethics. The DSMB composition, its remit, and frequency of data review were further defined in the Moderna mRNA-1273 DSMB Charter and DSMB Analysis Plan (Appendix 16.1.13).

- In addition to blinded and unblinded review of safety data, at each data review meeting the DSMB reviewed the numbers and rate of COVID-19 cases, including rate of severe COVID-19 disease with prespecified thresholds for imbalance in the treatment groups which would have triggered halting rules.
- At the IAs, the DSMB reviewed the IA of efficacy results and made recommendations to an Oversight Group in terms of study results reporting and unblinding based on the boundaries of early efficacy. The Oversight Group was comprised of a voting member each from the Sponsor, BARDA, and NIAID.
- The DSMB monitored the study for non-efficacy at the IA. The boundary for non-efficacy was non-binding and was provided in the DSMB analysis plan.
- The DSMB also monitored the study for vaccine harm based on both COVID-19 and severe COVID-19. Continuous harm monitoring was provided for COVID-19 and severe COVID-19 separately. For harm monitoring, cases were counted starting after the first dose of study IP. Boundaries were provided based on the exact 1-sided binomial tests conditional on the total number of cases under the assumption of VE=0%. If the prespecified stopping boundary was reached for either COVID-19 or severe COVID-19, then the unblinded statisticians would have immediately informed the DSMB that the harm rules had been met.

The boundaries were considered guidelines, ie, a recommendation to modify the study would not have been based solely on statistical rules, as many other factors (ie, totality of the data from the study including additional efficacy, safety, and immunogenicity endpoints as well as data external to the study) may have been part of the decision process. In the case of a recommendation to continue the trial regardless of crossing the boundaries for efficacy or

inefficacy, the reason for disregarding the boundary must have been documented in the meeting minutes and communicated to the Sponsor.

After each data review meeting or IA, the DSMB made a recommendation to the Sponsor through an Oversight Group to take 1 of the following courses of action:

- Stop further enrollment due to meeting criteria for early efficacy or due to a safety concern.
- Pause enrollment and consider a change in study design.
- Continue enrollment and/or study conduct as planned.

The Sponsor may also have requested that the DSMB conduct ad hoc reviews of safety events from this study or other data, including new nonclinical or clinical information related to mRNA-1273 external to this study. The DSMB reviewed all available study data to adjudicate such events in accordance with the DSMB charter.

3.8.4.3 Adjudication Committee

An Adjudication Committee (AC) was assembled for the purpose of reviewing potential cases to determine if the criteria for the primary and secondary endpoints was met. The AC remained blinded to treatment assignment. The AC comprised 4 physicians (inclusive of the committee chair) who were independent of the Sponsor. The AC composition, its remit, and frequency of data review were further defined in the Moderna mRNA-1273-P301 AC Charter.

3.8.5 Risk Management

This study was conducted according to ICH E6(R2) risk and quality processes, as described by the ICH guidance documents. The predefined quality tolerance limits (PDQTLs) being monitored throughout this study include the following:

- **Parameter name:** Proportion (%) of participants enrolled that are missing the second vaccination for any reason.

  Frequency: First run when approximately 10% of participants reached Day 29. Subsequent runs at 10% increments until all participants passed Day 29.

- **Parameter name:** Proportion (%) of participants enrolled that have a study discontinuation reason of either: lost to follow-up, withdrawal of consent by participant, physician decision, or other.

Frequency: First run when approximately 10% of participants completed the End of Study/Study Discontinuation page. Subsequent runs at 10% increments until all participants completed the End of Study/Study Discontinuation page.

- **Parameter name:** Proportion (%) of participants enrolled with any blood sample for immunogenicity serologic analysis not collected up to participant completion or discontinuation

Frequency: First run when approximately 10% of participants completed Day 1. Subsequent runs when approximately 10% of participants reached the following milestones: Day 29, Day 57, and End of Study/Study Discontinuation. Thereafter, subsequent runs when approximately 20% reached End of Study/Study Discontinuation followed by 20% increments until all participants completed the End of Study/Study Discontinuation page.

3.8.6 Clinical COVID-19 Response

The following is a summary of the mitigations the study team executed to reduce and/or eliminate the impact of COVID-19 on the study, sites and participants.

- Currently, the COVID-19 pandemic impact to this study has been low and manageable.
- PPD COVID review board has approved all CRA for travel to sites that allow onsite visits as an exception to their corporate travel restrictions for this study.
- As of 2 Nov 2020, a small number of the sites have restrictions for onsite visits for unblinded and blinded monitors. We are conducting remote visits while restrictions are in place.
- Monitoring for impact across all study sites is conducted as part of the remote and onsite monitoring procedures. Contract Research Organization is responsible to poll all sites regularly on COVID-19 impact to participants and study operations.
- Protocol design accommodates the reality of the virus and was in place prior to start of enrollment.
- Routine COVID-19 site impact and travel restriction updates are captured by CRO and provided in reports to Sponsor.
- Site specific concerns are documented in Monitoring Visit Reports.

- The EOS CSR will contain all COVID-19 impacts and protocol deviations per FDA guidance.

The framework for business continuity in response to the pandemic while conducting the mRNA-1273-P301 clinical study are provided in the Clinical COVID-19 Response document.

4 STATISTICAL ANALYSIS METHODS PLANNED IN THE PROTOCOL AND DETERMINATION OF SAMPLE SIZE

4.1 Statistical Methods

All analyses were conducted using SAS software (SAS Institute, Inc, Cary, North Carolina) Version 9.4. The final mRNA-1273-P301 SAP, Version 1.0 (dated 08 Sep 2020) and Version 2.0 (dated 08 Mar 2021) are provided in Appendix 16.1.9.

4.1.1 General Considerations

Continuous variables were summarized using the number of participants (n), mean, standard deviation, median, minimum, and maximum. Categorical variables were summarized using counts and percentages.

Baseline value, unless specified otherwise, was defined as the most recent nonmissing measurement (scheduled or unscheduled) collected before the first dose of IP.

Baseline SARS-CoV-2 status was determined by using virologic and serologic evidence of SARS-CoV-2 infection on or before Day 1.

- Positive SARS-CoV-2 status at baseline was defined as a positive RT-PCR test for SARS-CoV-2, and/or a positive serology test based on bAb specific to SARS-CoV-2 N-protein (as measured by Roche Elecsys anti-SARS-CoV-2 assay) on or before Day 1.
- Negative status at baseline was defined as a negative RT-PCR test for SARS-CoV-2 and a negative serology test (as measured by Roche Elecsys anti-SARS-CoV-2 assay) at Day 1.
- The baseline SARS-CoV-2 status was defined as missing for participants with both tests missing, or with 1 test missing and 1 test negative.
- Participants with negative baseline SARS-CoV-2 status were included in the modified intent-to-treat (mITT) Set; participants with positive or missing baseline SARS-CoV-2 status were excluded from the mITT and PP Sets.

The 2 treatment groups used for summary purposes for Part A were mRNA-1273 and placebo. If a participant received any dose of mRNA-1273 at any injection, regardless of the treatment group in which the participant was randomized, the participant was included in the mRNA-1273 group as the actual treatment group received for safety analyses.

The following analysis periods and treatment groups were used for efficacy analyses for Part A:

Part A Group	Description	Blinded/Part A Analysis Period for Efficacy
mRNA-1273	Participants randomized to mRNA-1273 in the randomized, placebo-controlled, blinded phase	From randomization to earlier date of Participant Decision Visit (unblinding, study discontinuation, study completion, death, or data cutoff date for efficacy)
Placebo	Participants randomized to placebo in the randomized, placebo-controlled, blinded phase	

The following analysis period and treatment groups were used for safety analyses for Part A:

Part A Group	Description	Blinded/Part A Analysis Period for Safety
mRNA-1273	Participants received at least 1 dose of mRNA-1273 in the randomized, placebo-controlled, blinded phase	From the first dose of study investigational product (IP) to the earlier date of (study discontinuation, study completion, death, data cutoff for safety, Participant Decision Visit/unblinding) for those who did not receive study IP in Part B. For participants who received study IP in Part B, from the first dose of study IP in study to the earlier date of (data cutoff for safety, or first IP injection in Part B)
Placebo	Participants only received placebo in the randomized, placebo-controlled, blinded phase	

The above analysis period for safety analysis in Part A was also referred to as "Overall Period" in the tables and listings (hereafter referred to as "Part A" in the CSR). Within Part A, "up to 28 days after any vaccination" includes the day of each vaccination through the 27 subsequent days, or up to the day of subsequent vaccination (if applicable). This time period was used as the primary analysis period for safety analyses, including solicited AR (Day 1 through Day 7 the first and second injections) and unsolicited AE (Day 1 through Day 28 after any injection), unless specified otherwise.

4.1.1.1 Statistical Hypothesis

For the primary efficacy objective, the null hypothesis for this study was that the VE of mRNA-1273 to prevent first occurrence of COVID-19 was ≤ 30%; ie,

$$H_0^{\text{efficacy}}: VE \leq 0.3.$$

The study was considered to have met the primary efficacy objective if the confidence interval (CI) of VE ruled out 30% at either one of the IAs or at the primary analysis.

4.1.2 Determination of Sample Size

The sample size was driven by the total number of cases to demonstrate the VE (mRNA-1273 vs. placebo) to prevent COVID-19. Under the assumption of proportional hazards over time and with 1:1 randomization to vaccine:placebo, a total of 151 COVID-19 events would provide 90% power to detect a 60% reduction in hazard rate, rejecting the null hypothesis H_0:VE ≤ 30%, with 2 IAs planned at 35% and 70% of the total events using a 1-sided O'Brien-Fleming boundary for efficacy and a log-rank test statistic with a 1-sided false positive error rate of 0.025. The total number of cases pertained to the PP Set, starting 14 days after the second dose of IP. Under specified assumptions, as detailed in mRNA-1273-P301 Clinical Study Protocol Section 9.3 (Appendix 16.1.1), up to approximately 30,000 participants were planned for randomization, and the time required was expected to be approximately 5, 8, and 10 months from study start (first participant first dose) to accrue 35% (approximately 53), 70% (approximately 106), and 100% (151), respectively, of the target number of cases in the PP Set.

For the secondary objective on the VE against serologically confirmed SARS-CoV-2 infection or COVID-19 regardless of symptomatology or severity (COV-INF), the study had ≥ 90% power to demonstrate the VE was above 30% (to reject null hypothesis VE ≤ 30%) at 1-sided alpha of 2.5% if the true VE to prevent COV-INF was 60%, because every COVID-19 disease endpoint was necessarily a COV-INF endpoint. For the secondary objective on the VE against severe COVID-19, the power depended on the number of severe COVID-19 cases (mRNA-1273-P301 Clinical Study Protocol Table 7; Appendix 16.1.1).

4.1.3 Analysis Sets

The following analysis sets were defined:

- **Randomized Set:** All participants who were randomized, regardless of the participant's treatment status in the study. Participants were analyzed according to the treatment group to which they were randomized.
- **Full Analysis Set (FAS):** All randomized participants who received at least 1 dose of IP. Participants were analyzed according to the treatment group to which they were randomized.

- **mITT Set:** All participants in the FAS who had no immunologic or virologic evidence of prior COVID-19 (negative SARS-CoV-2 status, ie, negative NP swab test and negative bAb against SARS-CoV-2 N-protein as measured by Roche Elecsys) at Day 1 before the first dose of IP; ie, all FAS participants excluding those with RT-PCR and/or serology positive at baseline (Day 1 before the first dose of IP). Participants were analyzed according to the treatment group to which they were randomized.
- **PP Set:** All participants in the mITT Set who received planned doses of IP per schedule and had no major protocol deviations, as determined and documented by the Sponsor prior to database lock and unblinding, which impacted critical or key study data. Participants were analyzed according to the treatment group to which they were randomized. Participants who did not receive the second injection of IP within [21, 42] days after the first injection date were excluded from the PP Set.
- **Immunogenicity Subset and Analysis Populations for Immunogenicity:** For characterizing immunogenicity of the vaccine and for assessing correlates of risk and protection, a case-cohort sampling design was used for measuring bAb and nAb data from a randomly sampled subset of study participants (the case-cohort Immunogenicity Analysis Set [ccIAS]) or immunogenicity subset. The ccIAS cohort consisted of a stratified, random sample of study participants (random subcohort) augmented with a subset or all primary endpoint cases and SARS-CoV-2 infection endpoint cases. The immunogenicity samples of the ccIAS cohort were processed and the immunogenicity data were available for the ccIAS cohort. The immunogenicity subset consisted of all participants in the ccIAS who had a valid baseline immunogenicity test result (prior to the first dose of IP) and at least 1 valid post-baseline result.

  The analysis of characterizing immunogenicity of mRNA-1273 is provided in Section 4.2.4.
- The **Per-Protocol Random Subcohort for Immunogenicity** (PPRSI) was used as the analysis population to characterize immunogenicity of mRNA-1273. The PPRSI for immunogenicity consisted of participants in the FAS who were sampled into the random subcohort and

  a) Received both planned doses (ie, received the treatment as the participant was randomized to) with Dose 2 received within [21, 42] days after Dose 1, and

  b) No major protocol deviation that impacted critical or key data.

Details of the case-cohort sampling and analysis populations for characterizing immunogenicity of mRNA-1273 are also provided in mRNA-1273-P301 SAP Section 6.7 (Appendix 16.1.9).

- **Solicited Safety Set:** All randomized participants who received at least 1 dose of IP and contributed any solicited AR data; ie, had at least 1 post-baseline solicited safety (eDiary) assessment. The Solicited Safety Set was used for the analyses of solicited ARs, and participants were included in the treatment group corresponding to the study vaccination they actually received.

  In addition, the following Solicited Safety Set was defined for each injection separately. **The First (Second) Injection Solicited Safety Set** consisted of all participants in the Solicited Safety Set who received the first (second) study injection and contributed any solicited AR data (eDiary) from the time of first (second) study injection through the following 6 days.

  Participants were analyzed according to the treatment group a participant received, rather than the treatment group to which the participant was randomized. If a participant was randomized to placebo but received any dose of mRNA-1273 vaccine at any injection, the participants were included in the mRNA-1273 group in the Solicited Safety Set.

- **Safety Set:** All randomized participants who received at least 1 dose of IP. The Safety Set was used for all analysis of safety except for the solicited ARs. Participants were included in the treatment group corresponding to the IP they actually received. For a participant who was randomized to placebo but received any dose of mRNA-1273 at any injection, the participant will be included in the mRNA-1273 group in the Safety Set.

4.1.4 Handling of Withdrawals of Consent, Lost to Follow-Up, and Missing Data

Imputation rules for missing or partial dates for prior and concomitant medications, non-study vaccinations, and procedures are provided in mRNA-1273-P301 SAP Appendix C, and imputation rules for missing AE dates are provided in mRNA-1273-P301 SAP Appendix D (Appendix 16.1.9).

For the secondary objective to characterize immunogenicity of mRNA-1273, for the binding and neutralizing anti-SARS-CoV-2 assays, if the laboratory results were reported as below the LLOQ (eg, < 0.1), the numeric values were imputed by 0.5 × LLOQ in the summary when treating the results as continuous variables. If the laboratory results were reported as greater than the ULOQ (eg, > 3,000), the numeric values were substituted by ULOQ in the summary when treating the

results as continuous variables. If the actual values above the ULOQ were provided by the testing laboratory, the actual values were used in the analysis and reporting.

Other incomplete/missing data were not imputed, unless specified otherwise.

4.1.5 Planned Analyses and Analyses of Efficacy Analyses That Have Been Conducted

4.1.5.1 Planned Interim Analyses and Primary Analysis

Two IAs were planned in this study: the first and second performed when approximately 35% and 70%, respectively, of the target total number of COVID-19 cases across the 2 treatment groups were observed. The primary objective of the IAs was for early detection of reliable evidence that VE was above 30%. The Lan-DeMets O'Brien-Fleming approximation spending function was used for calculating efficacy bounds and to preserve the (1-sided) 0.025 false positive error rate over the 2 IAs and the primary analysis (when the target number of cases was observed), relative to the null hypothesis ($H_0^{efficacy}$: VE ≤ 30%).

There was no intention to stop the study early if efficacy was demonstrated at any of the IAs. If efficacy was demonstrated at an IA, the subsequent IA or primary analysis was to be considered supportive in nature. The DSMB was to review the IA results and make recommendations to the Sponsor in terms of study results reporting and unblinding based on the boundaries of early efficacy as described in this section, safety data, and data external to this study. In addition to possible early efficacy at IAs, the DSMB monitored for non-efficacy and vaccine harm; the guiding principles (non-binding) is provided in Section 3.8.4.2.

The first IA was planned to occur when 35% of the total cases in the PP Set were observed. The study was to be considered positive at this IA if the 1-sided *p* value for rejecting VE ≤ 30% (hazard ratio [HR] ≥ 0.7) was less than 0.0002 based on the Lan-DeMets O'Brien-Fleming approximation spending function. This corresponded to an observed HR of approximately 0.259, or an observed VE of approximately 0.741.

The second IA was planned to occur when 70% of the total cases were observed in the PP Set. The study was to be considered positive at this IA if the *p* value for rejecting VE ≤ 30% (HR ≥ 0.7) was less than 0.0073 based on the Lan-DeMets O'Brien-Fleming approximation spending function. This corresponded to an observed HR of approximately 0.435, or an observed VE of approximately 0.565.

The primary analysis was to be performed when approximately 151 cases were observed in the PP Set. The study was to be considered positive at the primary analysis when a total of 151 cases were observed and if the 1-sided *p* value for rejecting HR ≥ 0.7 was less than 0.0227. This

corresponded to an observed HR of approximately 0.505, or observed VE of approximately 0.495.

As described in Section 3.6.4, an independent, unblinded statistics team, not involved in either study design or the regular study conduct, carried out the IAs.

4.1.5.2 Analyses of Efficacy That Have Been Conducted

4.1.5.2.1 The First Interim Analysis

The primary efficacy endpoint of mRNA-1273-P301 was based on confirmed clinical cases of COVID-19 per AC assessments (adjudicated cases), defined as the first occurrence of COVID-19 starting 14 days after the second injection.

For the primary efficacy objective, the null hypothesis of this study was that the VE of mRNA-1273 to prevent the first occurrence of COVID-19 was ≤ 30%, ie $H_0^{efficacy}$: VE ≤ 0.3.

The first IA was conducted based on a data snapshot that occurred on 11 Nov 2020 (DS1), and the data cutoff date for evaluation of efficacy was 07 Nov 2020. At the first IA, the median follow-up time was 49 days (7 weeks). The primary analysis of COVID-19 was based on the PP Set with cases starting 14 days after the second dose. The first interim efficacy analysis was performed by the independent biostatistician and the results were first reviewed by the independent external DSMB on 15 Nov 2020. The DSMB concluded that "with 63% of the expected number of the total number of adjudicated primary endpoints, the study has passed the efficacy monitoring boundary for benefit." The DSMB "encourages the study team to prepare the data for the FDA package as rapidly as possible." Based on the DSMB's recommendation, select Sponsor and CRO personnel were unblinded to prepare for regulatory submissions.

At the first IA, the total number of adjudicated COVID-19 cases starting 14 days after the second injection (ie, primary efficacy endpoint) was 95, 63% of the information fraction based on the total target number of 151 cases. Correspondingly, the nominal 1-sided alpha was 0.0047. At the first IA, the 1-sided *p* value to test the null hypothesis of VE ≤ 30% from the stratified Cox proportional hazard model was < 0.0001 and was compared to the nominal 1-sided alpha (0.0047) based on the number of cases at the first IA (95 in total). Equivalently, the lower bound of the alpha-adjusted CI of VE, the 2-sided 99.1% CI, could be compared to 30% at the first IA. The lower bound of the 2-sided 99.1% CI was above 30% at the first IA.

The VE of mRNA-1273 was demonstrated at the first IA based on the prespecified success criterion on efficacy (Section 6.1.1). Since efficacy was demonstrated at the first IA based on 95 adjudicated cases, all subsequent efficacy analyses were considered supportive or supplementary.

4.1.5.2.2 Primary Analysis of Efficacy

A second analysis was performed, that included data with a median follow-up duration for safety and efficacy of at least 2 months after completion of the full vaccination regimen. The analysis was based on a data snapshot as of 25 Nov 2020 (DS2), using a data cutoff date of 21 Nov 2020 for the evaluation of efficacy. Both safety and efficacy analyses were performed to provide additional information on the vaccine's profile. Since efficacy was demonstrated at the first IA, the primary analysis of efficacy based on DS2 was supplementary in nature.

All potential COVID-19 cases starting 14 days after the second injection confirmed by RT-PCR (central or local), were prioritized for adjudication. Corresponding available clinical data in electronic data capture as of 21 Nov 2020, were sent to the AC and were adjudicated for this analysis.

It was anticipated that the total number of adjudicated COVID-19 cases starting 14 days after the second injection in the PP Set at DS2 occurred on 25 Nov 2020 would be ≥ 151, the target total number of events at the originally planned primary analysis. At DS2, the total number of adjudicated COVID-19 cases starting 14 days after the second injection in the PP Set was 196 (Section 6.1.1). Therefore, this analysis was considered the primary analysis of efficacy including at least 151 cases, as prespecified in the protocol.

4.1.5.3 Final Analysis of Efficacy for Blinded Data (Part A)

Results from the first IA based on DS1 and the primary analysis based on DS2 were used to support the EUA application in the US and other regions of the world. The EUA was authorized for mRNA-1273 in the US on 18 Dec 2020.

The mRNA-1273-P301 Clinical Study Protocol Amendment 6 (dated 23 Dec 2020; Section 3.2.1) informed all ongoing study participants of the availability of and eligibility criteria for any COVID-19 vaccine made available under an EUA. The amendment also allowed study sites to offer participants who originally received placebo in this study the potential benefit of vaccination against COVID-19, given that the primary efficacy endpoint for mRNA-1273 against COVID-19 was met per the protocol-defined IA. Participants in this study underwent a PDV, at which they had the opportunity to be unblinded, and those originally randomized to placebo had the opportunity to receive mRNA-1273 in this study.

A final analysis of efficacy was performed when a median follow-up of at least 6 months had occurred. At this time, at least 90% of the study participants who had completed the PDV or had been unblinded or discontinued from the study provided efficacy data based on Part A, the randomized, placebo-controlled, blinded phase of the study. The final analysis of efficacy for Part A was based on database lock of 04 May 2021, and included available participant level data

up to early unblinding, study discontinuation, the Part B PDV or data cutoff date (26 Mar 2021), whichever was earlier. Additionally, for secondary efficacy endpoints of SARS-CoV-2 infection regardless of symptomology and severity (all infection) and asymptomatic SARS-CoV-2 infection, separate analyses were performed including new positive RT-PCR results at the PDV.

4.1.6 Multiplicity Adjustments

The overall type I error rate for this study was controlled at 2.5% (1-sided). The overall type I error rate for the primary efficacy endpoint at the IAs and the primary analysis was strictly controlled at 2.5% (1-sided) based on the Lan-DeMets O'Brien-Fleming approximation spending function. The primary efficacy endpoint was considered statistically significant after consideration of the strategy for controlling the type I error as described in Section 4.1.5.1. Statistical significance of the primary efficacy endpoint can be achieved at either 1 of the IAs or at the primary analysis.

A sequential/hierarchical testing procedure was planned to control type 1 error rate over the primary efficacy endpoint and the secondary efficacy endpoints. Secondary efficacy endpoints were only tested when the primary efficacy endpoint achieved statistical significance.

If the primary efficacy endpoint achieved statistical significance at either one of the IAs or at the primary analysis, a fixed-sequence statistical strategy was used to test the following secondary efficacy endpoints in a predefined order:

1. Secondary efficacy endpoint: COVID-19 regardless of evidence of prior SARS-CoV-2 infection at the same analysis (through the same follow-up period)
2. Secondary efficacy endpoint: infection regardless of symptomatology or severity at the same analysis (through the same follow-up period)
3. Secondary efficacy endpoint: severe COVID-19 at the analysis with ≥ 20 cases, otherwise, to test at the end of the study

The sequential tests of the above 3 secondary efficacy endpoints were to be performed at 1-sided type I error rate of 0.025, if the primary efficacy endpoint achieved statistical significance at either one of the IAs or at the primary analysis. Please refer to mRNA-1273-P301 SAP Section 6.5 (Appendix 16.1.9).

A graphical overview of the testing strategy planned testing of primary and select secondary efficacy endpoints is provided in mRNA-1273-P301 SAP Figure 2 (Appendix 16.1.9).

At the IA where VE for COVID-19 was demonstrated at the prespecified statistical criterion, there were 11 total adjudicated severe COVID-19 cases starting 14 days after the second injection.

At the time of the IA and the primary analysis of efficacy, data for secondary efficacy endpoint infection regardless of symptomatology or severity were not available and were not included in these analyses.

4.1.7 Multicenter Studies

No analyses were performed based on grouping or excluding any of the study centers.

4.1.8 Adjustment for Covariates

Adjustments for covariates were performed for the primary efficacy analyses as described in Section 4.2.2.1 and Section 4.2.2.1.4.

4.1.9 Examination of Subgroups

Subgroup analyses of the efficacy, safety, and immunogenicity endpoints are described in Section 4.2.2, Section 4.2.3, and Section 4.2.4, respectively.

4.2 Population, Efficacy, Safety, and Immunogenicity Statistical Analyses

4.2.1 Study Population

4.2.1.1 Disposition

The number and percentage of participants in the following categories were summarized by treatment group based on the Randomized Set: Randomized Set, FAS, mITT Set, PP Set, Solicited Safety Set, and Safety Set. The denominators for the percentages were based on participants in the Randomized Set.

The number of participants in the following categories were summarized based on participants screened: number of participants screened; and number and percentage of screen failure participants and the reason for screen failure.

The number and percentage of randomized participants were summarized separately by stratification factor at randomization (ie, ≥ 18 and < 65 years and not at risk, ≥ 18 and < 65 years and at risk, or ≥ 65 years) based on the Randomization Set.

The number and percentage of participants in each of the following disposition categories were summarized based on the Randomized Set: received each dose of IP, prematurely discontinued before receiving the second dose of IP and the reason for discontinuation, completed study, and prematurely discontinued the study and the reason for discontinuation.

A listing was provided for participants with any inclusion and exclusion criteria violation.

4.2.1.2 Protocol Deviation

Major protocol deviations were defined as a subset of protocol deviations that significantly impacted the completeness, accuracy, or reliability of the study data or that significantly affected a participant's rights, safety, or well-being. Major protocol deviations rules were developed and finalized before database lock. The major protocol deviations are described in Section 5.4.

The number and percentage of the participants with each major protocol deviation type were summarized by treatment groups based on the Randomized Set.

Select major protocol deviations impacted critical or key study data, and participants with such deviations were excluded from the PP Set for efficacy analyses; major protocol deviations were determined and documented by the Sponsor prior to database lock and unblinding. Reasons of exclusion from the PP Set for efficacy were summarized.

4.2.1.3 Demographics and Baseline Characteristics

Descriptive statistics were calculated for the following continuous demographic and baseline characteristics: age (years), weight (kg), height (cm), and BMI (kg/m^2). The number and percentage of participants were provided for categorical variables, such as age group, sex, race, ethnicity, randomization stratum under which the participant was randomized, and the following risk factors at screening (at least 1 of the following):

- Chronic lung disease (eg, emphysema and chronic bronchitis, idiopathic pulmonary fibrosis, and cystic fibrosis) or moderate to severe asthma
- Significant cardiac disease (eg, heart failure, coronary artery disease, congenital heart disease, cardiomyopathies, and pulmonary hypertension)
- Severe obesity (BMI ≥ 40 kg/m^2)
- Diabetes (type 1, type 2, or gestational)
- Liver disease
- HIV infection

The summaries were presented separately based on the FAS, Safety Set, mITT Set, and PP Set.

4.2.1.4 Medical History

Medical history data were coded by system organ class (SOC) and preferred term (PT) according to the MedDRA version 23.0.

The number and percentage of participants with any medical history were summarized by SOC and PT based on the Safety Set. A participant was counted only once for multiple events within each SOC and PT. The SOCs were displayed in internationally agreed order. The PTs were displayed in descending order of frequency of mRNA-1273 and then alphabetically within SOC.

4.2.1.5 Prior, Concomitant, and Post Medications

Prior and concomitant medications and non-study vaccinations were coded using the WHODrug, version March 2020.The summary of concomitant medications was based on the Safety Set. Categorization of prior, concomitant, and post medications was summarized in mRNA-1273-P301 SAP Appendix C (Appendix 16.1.9).

The number and percentage of participants who continued or newly received concomitant medications and non-study vaccinations were summarized by treatment group by PT in descending frequency in the mRNA-1273 group as follows:

- Any concomitant medications.
- Any non-study vaccine.
- Antipyretic or analgesic medications were summarized during the 7-day follow-up period of each injection and during the 28-day follow-up period after each injection (for first injection, up to second injection or 28 days after the first injection).

Prior, concomitant, and post medications and non-study vaccinations were presented in a listing.

4.2.1.6 Exposure

The number and percentage of participants who received the first and second injections were summarized by treatment group. The timing of the second injection was also summarized by treatment group.

4.2.2 Efficacy Analyses

The PP Set was the primary analysis population for efficacy analyses, unless otherwise specified. In the PP Set, mITT Set, and FAS used for all efficacy analyses, participants were included in the treatment group which they were randomized to.

COVID-19 is defined as symptomatic disease meeting clinical criteria based both on symptoms for COVID-19 and positive RT-PCR test results; mRNA-1273-P301 Clinical Study Protocol Section 8.1.1 (Appendix 16.1.1) for the eligible symptoms for COVID-19 cases. The AC, blinded to treatment assignment, reviewed potential cases and adjudicated COVID-19 and severe COVID-19 cases. The AC assessments were used in the first IA based on DS1 that occurred on

11 Nov 2020 (Section 4.1.5.2), the primary analysis based on DS2 that occurred on 25 Nov 2020 (Section 4.1.5.2.2), and the final efficacy analysis of Part A data based on database lock that occurred on 04 May 2021 (Section 4.1.5.3).

Baseline SARS-CoV-2 status (Section 4.1.1), RT-PCR test results at baseline, serology status at baseline (bAb specific to SARS-CoV-2 N-protein, as measured by Roche Elecsys anti-SARS-CoV-2 assay) were summarized by treatment group.

The mITT and PP Sets only included participants with baseline negative SARS-CoV-2 status.

The RT-PCR test results and bAb specific to SARS-CoV-2 N-protein were summarized by visit.

4.2.2.1 Analysis of the Primary Efficacy Endpoint

4.2.2.1.1 Primary Efficacy Endpoint Definition and Derivation

The primary efficacy objective is the VE of mRNA-1273 to prevent occurrence of COVID-19 starting 14 days after the second dose of IP (Section 2).

The determination of COVID-19 cases for the primary efficacy analysis is summarized in Table 4-1.

An AC blinded to treatment assignments reviewed potential cases and adjudicated COVID-19 and severe COVID-19 events, and the date of COVID-19 and severe COVID-19. Two sets of COVID-19 cases were provided:

- Based on the assessment of the AC
- Based on eligible COVID-19 symptoms (at least 2 systemic symptoms or 1 respiratory symptom) and positive RT-PCR

Table 4-1: Determination of COVID-19 Cases (Primary Efficacy Endpoint)

	COVID-19
Post-baseline PCR results at Illness Visits prompted by symptom(s)	Positive, **AND**
Systemic symptoms	At least **TWO** of the following **systemic symptoms**: fever (≥ 38ºC), chills, myalgia, headache, sore throat, new olfactory and taste disorder(s); **OR**
Respiratory symptoms	At least **ONE** of the following **respiratory** signs/symptoms: cough, shortness of breath or difficulty breathing, OR clinical or radiographical evidence of pneumonia

Abbreviations: PCR = polymerase chain reaction.

The onset date of a documented COVID-19 case was the later date of 2 eligible systemic symptoms reported, or 1 eligible respiratory symptom reported and date of positive PCR test. The time to the first occurrence of COVID-19 was calculated as ([Date of documented COVID-19] – [Date of randomization] + 1).

In the primary analysis approach for the primary efficacy endpoint, cases were counted starting 14 days after the second injection. In the various sensitivity analyses planned to examine the onset of COVID-19, the censoring rules of cases are outlined in Table 4-2.

In Part A, there was a scheduled NP swab test at the Day 29 visit prior to the second injection of IP. In addition, serum samples for bAb against SARS-CoV-2 N-protein are being tested at Months 1, 2, 7, 13, and 25. At the IA and the primary analysis of efficacy, the RT-PCR results at Day 29 and bAb against SARS-CoV-2 N-protein at Month 1 were not considered in the determination of COVID-19 cases.

At the final blinded efficacy analysis, participants with early infection, as detected by positive RT-PCR at Day 29 or positive bAb against SARS-CoV-2 N-protein in blood samples at the scheduled visits, were censored (ie, the event did not occur for the analysis) at the time of early infection. If a participant had eligible symptom(s) within 14 days of positive RT-PCR at the scheduled Day 29 visit, the participant was considered to be a case for COVID-19.

Additional details on the primary endpoint definition and derivation are provided in the mRNA-1273-P301 SAP Section 6.3.1.1 (Appendix 16.1.9).

4.2.2.1.2 Primary Analysis Approach

The number and percentage of participants who had an event (ie, the first occurrence of COVID-19 starting 14 days after the second injection) and the participants who were censored were summarized.

The non-parametric Kaplan-Meier method was used to estimate the time to first occurrence of COVID-19 curve in each treatment group.

Vaccine efficacy was defined as the percent reduction in the hazard of the primary endpoint (mRNA-1273 vs. placebo), ie, 1 – HR. The null hypothesis was:

$$H_0^{efficacy}: VE \leq 0.3$$

Equivalently, the null hypothesis was:

$$H_0^{efficacy}: HR \geq 0.7$$

A stratified Cox proportional hazard model with Efron's method of tie handling and with treatment group as covariate was used to assess the magnitude of the treatment group difference (ie, HR) between mRNA-1273 and placebo. The same stratification factors used for randomization (Section 3.6.3) were applied to the stratified Cox model. The VE with corresponding alpha-adjusted CI, 95% CI, and 1-sided *p* value for testing the null hypothesis from the stratified Cox model was reported at a planned IA up to the analysis at which VE was demonstrated. After VE was demonstrated, VE and 95% CI were to be provided for subsequent analysis/updates of efficacy.

In this study, VE was demonstrated based on prespecified statistical criterion (Section 4.1.5) at the IA, at which, 1-sided *p* value for testing the null hypothesis of VE ≤ 0.3, 95% CI, and alpha-adjusted CI were provided from the stratified Cox model. At the primary analysis where the total number of COVID-19 cases > 151, total target number of cases, VE, 1-sided *p* value for testing the null hypothesis of VE ≤ 0.3, and 95% CI were provided. In subsequent analysis/updates of efficacy, VE and 95% CI were provided.

For the primary analysis, participants who had no documented COVID-19 were censored at the last study assessment date (Table 4-2). Participants who discontinued the study early or died due to causes unrelated to COVID-19 without documented COVID-19 were censored at the date of early discontinuation or death. Participants who experienced an early COVID-19 up to 14 days after the second injection of IP were censored at the time of documented COVID-19.

The primary analysis population for efficacy is the PP Set.

The number and percentage of participants who had an event (ie, the first occurrence of COVID-19 at least 14 days after the second injection) were reported.

Potential intercurrent events to the estimand are listed in Section 4.2.2.1.6. The primary estimand is provided in Section 4.2.2.1.6, with rationale for strategies to address intercurrent events summarized in mRNA-1273-P301 SAP Appendix F (Appendix 16.1.9).

4.2.2.1.3 Sensitivity Analyses of Primary Efficacy Endpoint

Sensitivity analyses were performed, with COVID-19 cases counted starting at various time points using the PP Set as follows:

- After the second injection of IP
- Fourteen days after the first injection of IP (also as primary analysis approach for the secondary efficacy objective: to evaluate the efficacy of mRNA-1273 to prevent COVID-19 after the first dose of IP).
- After randomization

Please note, the 2 injections were to be given 28 days apart; the PP Set included participants who received the second injection within [21, 42] days after the first injection. In the sensitivity analysis after randomization, cases that occurred up to the second dose, from the second dose to 14 days after the second dose, as well as the cases that occurred beyond 14 days after the second dose were included.

The censoring rules for analyses of the primary endpoint are summarized in Table 4-2.

Table 4-2: Censoring Rules for COVID-19

Situation	Primary Efficacy Approach (Cases ≥ 14 Days After Dose 2)	Sensitivity Analyses			
		Cases Starting After Dose 2	Cases ≥ 14 days After Dose 1	Cases Starting After Dose 1[a]	Cases Starting After Randomization
Early case from randomization up to first injection	Censored at date of case	Censored at date of case	Censored at date of case	Censored at date of case	Event
Early case from Dose 1 up to (<) 14 days after Dose 1	Censored at date of case	Censored at date of case	Censored at date of case	Event	Event
Early case from ≥ 14 days after Dose 1 up to (<) Dose 2	Censored at date of case	Censored at date of case	Event	Event	Event
Early case from Dose 2 up to (<)14 days after Dose 2	Censored at date of case	Event	Event	Event	Event
Case ≥ 14 days after Dose 2	Event	Event	Event	Event	Event
Early discontinuation or death without documentation of COVID-19	Censored at date of discontinuation/death				
Early infection as detected by: positive RT-PCR at scheduled visit (pre-Dose 2), or, positive bAb against SARS-CoV-2 nucleocapsid protein in blood samples at the scheduled visits	Censored at date of early infection				

Abbreviations: bAb = binding antibody; RT-PCR = reverse transcription polymerase chain reaction.

[a] Was to be performed if there were ≥ 10% of total cases with Dose 1 date > randomization date.

Analysis of the primary efficacy endpoint based on the mITT Set was also performed using the same statistical methods used for the primary analysis. The sensitivity analyses, with COVID-19 cases counted starting at various time points were also performed using the mITT Set.

4.2.2.1.4 Subgroup Analyses of the Primary Endpoint

To assess consistency of VE across various subgroups, subgroup analyses of the primary efficacy endpoint were performed based on the PP Set. The primary efficacy endpoint was analyzed by each of the subgroups using the same methods described for the primary analysis (ie, stratified Cox proportional hazard model with Efron's method of tie handling with a single treatment covariate), and the estimate of VE and its 95% CI were provided within each category of the following subgroups:

- Age groups: ≥ 18 and < 65 years, ≥ 65 years

- Age groups: ≥ 18 and < 65 years, ≥ 65 years and < 75 years, ≥ 75 years
- Stratification factor at randomization: ≥ 18 and < 65 years and not at risk, ≥ 18 and < 65 years at risk, ≥ 65 years
- Sex (female, male)
- Race
- Ethnicity
- Race and ethnicity: non-Hispanic White, communities of color
- Each risk factor for severe COVID-19 illness as listed in Section 3.6.3

If the number of participants in certain subgroups was too small, it may have been combined with the other subgroups for the subgroup analyses. Forest plots were provided for VE and its 95% CI for the subgroup analyses based on the PP Set. Subgroup analyses based on the mITT Set were performed.

Recently, new SARS-CoV-2 variants have emerged. COVID-19 cases were sequenced and a summary of cases genotypically distinct and genotypically similar to vaccine by treatment assignment was provided. For specific variants with sufficient number of variant cases during the blinded phase of the study, competing risk method was used to estimate the VE of mRNA-1273, specifically, Fine and Gray's (FG) sub-distribution hazard model was used. COVID-19 cases of specific variant were considered as cases, and COVID-19 cases of variant other than that of interest were considered as competing events in this analysis.

4.2.2.1.5 Supportive Analysis of the Primary Analysis Using Exact Method Based on Incidence Rate

For each treatment group, the incidence rate was calculated as the number of participants with an event (ie, first occurrence of COVID-19 at least 14 days after the second injection) divided by the number of participants at risk, adjusted by person-time. The person-time was calculated as the time from randomization to the date of the first event for participants with an event, and the time from randomization to the date of censoring for participants without an event (or who were censored). Person-time, incidence rate, and 95% CI for incidence rate were provided by treatment group.

As a supportive analysis, the VE was also estimated by 1 – the ratio of incidence rate (mRNA-1273 vs. placebo), ie, 1 – ratio of incidence rate (mRNA-1273 vs. placebo) adjusting for person-time, and the 95% CI of VE were computed using the exact method conditional upon the total number of cases adjusting for person-time.

4.2.2.1.6 Estimands and Intercurrent Events

The estimand of the primary analysis was VE measured using 1 – HR (mRNA-1273 vs. placebo) for prevention of first occurrence of COVID-19 from 14 days after second dose of IP in adults. A hypothetical strategy was used for early discontinuation (eg, withdrawal consent, deaths unrelated to COVID-19) or early COVID-19 in participants in the PP Set. Potential intercurrent events to the estimand are provided in Table 4-3. A description of the primary estimand with rationale for strategies to address intercurrent events is summarized in mRNA-1273-P301 SAP Appendix F (Appendix 16.1.9).

Table 4-3: Intercurrent Event Types

Label	Intercurrent Event Type	Comment
Intercurrent Event 1 (early discontinuation or death without confirmation of cases, ie, unrelated death)	Early discontinuation from study preventing from confirmation of COVID-19, ie, unrelated death or withdrawal consent prior to documented confirmed COVID-19	Participants in the PP Set who withdrew consent or died due to unrelated to COVID-19 without confirmation of being a case were included in primary efficacy analysis.
Intercurrent Event 2 (early COVID-19)	COVID-19 starting up to 14 days after the second dose of IP	Participants in the PP Set who experienced an early COVID-19 up to 14 days after the second dose of IP were included in primary efficacy analysis.

Abbreviations: COVID-19 = coronavirus disease 2019; IP = investigational product; PP = per protocol.

4.2.2.2 Analyses of the Secondary Efficacy Endpoints

A sequential/hierarchical testing procedure was used to control type 1 error rate over the primary efficacy endpoint and the secondary efficacy endpoints. Secondary efficacy endpoints were only tested if the primary efficacy endpoint achieved statistical significance. As required, multiplicity adjustments among the secondary efficacy endpoints were performed for secondary efficacy endpoints as described in Section 4.1.6.

The secondary efficacy endpoints and definitions of severe COVID-19, secondary cases of COVID-19, and death attributed to COVID-19 are included in Section 2.

Similar analysis methods, as detailed for the primary efficacy endpoint (Section 4.2.2.1), were applied to the following secondary efficacy endpoints based on the PP Set, unless otherwise specified:

- VE to prevent severe COVID-19; details on the determination of this endpoint are presented in mRNA-1273-P301 SAP Section 6.3.2.1.1 (Appendix 16.1.9).

- VE to prevent serologically confirmed SARS-CoV-2 infection or COVID-19 regardless of symptomatology or severity; details on the determination of this endpoint are presented in mRNA-1273-P301 SAP Section 6.3.2.1.3 (Appendix 16.1.9).

  The analysis population for this endpoint, serologically confirmed SARS-CoV-2 infection or COVID-19 regardless of symptomatology or severity [COV-INF], was the PP Set (primary analysis population) and the mITT Set that included participants with negative SARS-CoV-2 status at baseline. Infection [COV-INF] was defined by any post-baseline positive RT-PCR results, and/or, seroconversion due to infection defined as positive bAb specific to SARS-CoV-2 NP as measured by Roche Elecsys at post-baseline scheduled visits for participants with negative SARS-CoV-2 status at baseline (PP and mITT Sets). Both RT-PCR tests from the scheduled NP swab tests at Day 29 as well as those prompted by symptom(s) were considered. A COVID-19 case or secondary definition of COVID-19 case was always a COV-INF case. The final analysis of efficacy for Part A included available participant level data up to early unblinding, study discontinuation, the Part B PDV or data cutoff date (26 Mar 2021), whichever was earlier. Separate analyses were also performed for SARS-CoV-2 infection or COVID-19 regardless of symptomatology or severity including new positive RT-PCR results at the PDV.

- VE to prevent COVID-19 using a secondary definition of symptoms; details on the determination of this endpoint are presented in mRNA-1273-P301 SAP Section 6.3.2.1.2 (Appendix 16.1.9).

- VE to prevent death caused by COVID-19

For each of the above secondary endpoints, the following analyses were performed:

- VE was estimated with 1 – HR (mRNA-1273 vs. placebo) using a Cox proportional hazard model based on the PP Set as described for the primary efficacy endpoint. Kaplan-Meier curves of time to event were presented for each treatment group. Cases were counted starting 14 days after the second injection of IP.

- Analysis was performed using the same model based on the mITT Set as described for the primary efficacy endpoint. Kaplan-Meier curves of time to event were presented for each treatment group.

- Sensitivity analyses were performed, with cases counted starting immediately after the second injection of IP (onset date ≥ date of second injection, considering positive RT-PCR at Day 29), starting 14 days (≥ 14 days) after the first injection of IP, and immediately after randomization, respectively.

- VE and 95% CI based on the incidence were estimated with 1 – ratio of incidence rates using the exact method conditional upon the total number of cases.

For the secondary efficacy objective: VE to prevent asymptomatic SARS-CoV-2 infection

- The analysis populations for asymptomatic infection were the PP Set (primary analysis population) and mITT Set. Asymptomatic infection was COV-INF (detected by positive RT-PCR or seroconversion [bAb specific to SARS-CoV-2 NP as measured by Roche Elecsys at scheduled visits]) with absence of symptoms.

  As diseased cases (COVID-19 or secondary definition of COVID-19) were competing events for asymptomatic SARS-CoV-2 infections, competing risk method (FG subdistribution hazard model) was used to estimate the VE of mRNA-1273. Competing risk method was also used to estimate the cumulative incidence function, and the cumulative incidence of asymptomatic SARS-CoV-2 infections were plotted.

  In the primary approach with cases of asymptomatic SARS-CoV-2 infection counted starting 14 days after the second injection, only seroconversion at Day 57 or later was to be considered. The final analysis of efficacy for Part A included available participant level data up to early unblinding, study discontinuation, the Part B PDV or data cutoff date (26 Mar 2021), whichever was earlier. Separate analyses were also performed for asymptomatic SARS-CoV-2 infection including new positive RT-PCR results at the PDV. Details on the determination of asymptomatic SARS-CoV-2 infection are provided in mRNA-1273-P301 SAP Section 6.3.2.1.4 (Appendix 16.1.9).

  As serum samples were taken at scheduled visits (eg, Day 29 [Month 1], Day 57 [Month 2], PDV), sensitivity analyses with cases counted starting after second injection, 14 days after the first injection, after the first injection, and after randomization were the same. Only 1 set of sensitivity analysis with cases counted starting from randomization was provided. In this sensitivity analysis, asymptomatic cases detected by positive RT-PCR result at scheduled Day 29 (before the second injection), or seroconversion at time points with scheduled visits were considered. Sensitivity analysis using the mITT Set with cases counted starting from 14 days after the second injection, and from randomization were also performed.

For the secondary efficacy objective: VE to prevent COVID-19 after the first injection of IP

- This endpoint was analyzed as a sensitivity analysis of the primary efficacy endpoint with cases counted starting 14 days (≥ 14 days) after the first injection of IP as described in Section 4.2.2.1.

For the secondary efficacy objective: VE to prevent COVID-19 disease regardless of prior SARS-CoV-2 infection

- VE to prevent COVID-19 disease regardless of prior SARS-CoV-2 infection was analyzed using the FAS. The same methods described for the primary efficacy endpoint (Section 4.2.2.1) were applied with cases counted starting 14 days after the second injection of IP.

  Sensitivity analyses with cases counted starting immediately after the second injection, 14 days after the first injection, and after randomization were also performed. In sensitivity analysis with cases counted starting after the second injection, participants who received only the first injection and were cases, were censored at the time of COVID-19.

  The VE was also estimated with 1 – the ratio of incidence rates with the 95% CI using the exact method conditional upon the total number of cases adjusting for person-time.

  In addition, an exploratory analysis with the same Cox model was performed in the subgroup of the FAS whose baseline SARS-CoV-2 status was positive with cases counted starting 14 days after the second dose to assess the VE in those with positive baseline SARS-CoV-2 status, at baseline, if sample size permitted. Such analysis in the subgroup of the FAS whose baseline SARS-CoV-2 status was negative with cases counted starting 14 days after the second dose was the same as the sensitivity analysis of COVID-19 starting 14 days after the second dose in the mITT Set.

4.2.2.3 Exploratory Efficacy Endpoint Analyses

Details of the analyses of exploratory objectives and endpoints included in this Part A CSR are described in the following sections.

4.2.2.3.1 Vaccine Efficacy Based on Duration and Presence/Severity of COVID-19 Symptoms

Participants reported symptoms including fever (temperature ≥ 38ºC), chills, cough, shortness of breath, difficulty breathing, fatigue, muscle aches (myalgia), body aches, headache, new loss of taste, new loss of smell, sore throat, nasal congestion, runny nose (rhinorrhea), nausea, vomiting, and diarrhea. The severity of these symptoms was graded according to the severity scoring system presented in mRNA-1273-P301 SAP Table 9 (Appendix 16.1.9). A score endpoint aggregating duration and presence/severity of COVID-19 symptoms were calculated as the sum of daily severity scores of all recorded symptoms across all days with symptoms. The VE of mRNA-1273 based on mean score of each treatment group was calculated as follows:

VE = [1 – Mean score of mRNA-1273 group / Mean score of placebo group] × 100%

A proportional means model including treatment group as fixed effect and stratified with stratification factor at randomization was used to assess the VE (mRNA-1273 vs. placebo) on the score aggregating duration and presence/severity of COVID-19 symptoms based on the PP Set. The score was summarized and categorized into quartiles (across the 2 groups) using 1, 2, 3, 4. The indication of the quartiles was used as the dependent variable in the proportional mean model.

4.2.2.3.2 Vaccine Efficacy Against Burden of Disease

Exploratory analysis of burden of disease (BOD) due to COVID-19 was performed. A BOD score was defined based on the post SARS-CoV-2 infection follow-up to reflect the worst severity of symptoms (0 [without COVID-19] to 3 [death]) as shown in mRNA-1273-P301 SAP Table 7 (Appendix 16.1.9).

A summary of BOD score and the number and percentage of participants with each level of BOD score was provided by treatment group using the PP Set.

To assess impact of baseline risk of severe disease on the vaccine effect regarding disease severity, summary of BOD were provided by randomization strata (ie, ≥ 65 years; < 65 years at risk; and < 65 years not at risk).

To assess the disease burden in participants with COVID-19, the summary of BOD was provided in participants with COVID-19, ie, participants with BOD score of zero were excluded from the analysis.

While transparent, the proportions in the summary table will change with increased follow-up time as more participants inevitably acquire disease. This makes comparisons across different periods of follow-up difficult. To augment this analysis, a proportional means model was used to assess the treatment effect on BOD between mRNA-1273 and placebo in terms of ratio of mean severity score. The proportional means model allowed for direct comparisons across different periods of follow-up, unaffected by differential follow-up. A proportional means model, including treatment group as fixed effect and stratified with stratification factor at randomization, was used to assess the vaccine effect on BOD. The VE for the BOD score was estimated as 1 – the ratio of means as estimated by the proportional means model and reported with 95% CIs.

4.2.2.3.3 Vaccine Efficacy Against Burden of Infection

To fully understand the impact of vaccination on disease severity, asymptomatic infections were also evaluated. Similarly, a burden of infection (BOI) score was calculated (0 [no infection] to

3 [death]) as shown in mRNA-1273-P301 SAP Table 8 (Appendix 16.1.9) and used to understand the impact.

Since asymptomatic infection was identified by seroconversion only at scheduled visits at which samples for RT-PCR test and/or serum samples were planned to be collected (eg, Months 1, 2, 7, 13, and 25), summary of BOI for relevant periods (eg, Baseline through Month 1, Month 1 through Month 2, Month 2 through Month 7, Month 7 through Month 13, and Month 13 through Month 25) was planned. With mRNA-1273-P301 Protocol Amendment 6 (Section 3.2.1), at the unblinding/PDV/OL-D1 visit, an NP swab for RT-PCR tests and serum samples was collected. The relevant periods were updated to Baseline through Month 1, Month 1 through Month 2, and Month 2 through Month 7/PDV, whichever was earlier.

A proportional means model, including treatment group as fixed effect and stratified with stratification factor at randomization, was used to assess the vaccine effect on BOI. The VE for BOI was estimated as 1 – the ratio of mean BOI scores and reported with 95% CIs.

4.2.2.3.4 Vaccine Efficacy on Viral Load

For the cohort of adjudicated COVID-19 cases, the Day 1 illness NP swab and the Days 3, 5, 6, 9, 14, 21, and 28 of illness saliva specimens were matched to assess the qualitative and quantitative result for each. Conversion from cycle time (CT) to viral copies for the quantitative RT-PCR were Log10ViralCopies=CT -40.9578)/-3.3385 for swabs (Day 1) and Log10ViralCopies = CT -41.0349)/-3.3346) for saliva (Days 3, 5, 7, 9, 14, 21, and 28). If the qualitative result was negative, the log10viral copies was assumed to be 0. A mixed-effect model repeated measures (MMRM) analysis was performed comparing absolute and change from baseline log10 viral load between vaccinated and placebo participants from the NP swab Day 1 of illness through saliva sample Days 3, 5, 7, 9, 14, 21, and 28 of illness. Only participants with a quantitative result in the Day 1 illness NP swab were included in the MMRM modeling. Any MMRM result estimate under 0 copies, was truncated at 0. There was no imputation for missing data.

4.2.2.3.5 Vaccine Efficacy to Prevent All-Cause Mortality

Vaccine efficacy to prevent all-cause mortality was analyzed using the Cox proportional hazard model (Section 4.2.2.1) based on the PP Set, mITT Set, and FAS. Death, regardless of cause, from randomization was included. Time to death was calculated as date of death – date of randomization + 1. Participants with no documented death were censored at the earliest date (last date of study participation, early discontinuation, or lost to follow-up).

4.2.3 Safety Analyses

Safety and reactogenicity were assessed by clinical review of all relevant parameters including solicited ARs (local and systemic), unsolicited AEs, SAEs, MAAEs, AEs leading to withdrawal from study vaccine and/or study participation, vital signs, and physical examination findings.

All safety analyses were based on the Safety Set, except summaries of solicited ARs, which were based on the Solicited Safety Set. All safety analyses were provided by treatment group, unless otherwise specified.

4.2.3.1 Solicited Adverse Reactions

Solicited ARs, including local and systemic ARs collected in the eDiary, are described in Section 3.7.4.1. Local and systemic solicited ARs were categorized based on the Toxicity Grading Scale for Healthy Adult and Adolescent Volunteers Enrolled in Preventive Vaccine Clinical Trials (DHHS 2007) as described in mRNA-1273-P301 Protocol Section 8.3.4 (Appendix 16.1.1).

All solicited ARs (local and systemic) were considered causally related to injection.

Analyses of solicited ARs were provided by treatment group for each injection (first or second) based on the associated subset of the Solicited Safety Set, ie, First (Second) Injection Solicited Safety Set and for any injection based on the Solicited Safety Set, unless otherwise specified.

The number and percentage of participants who reported each individual solicited local AR and solicited systemic AR during the 7-day follow-up period (or until resolution for solicited ARs that continued beyond 7 days) after each injection were provided by severity grade. The number and percentage of participants who reported each individual solicited AR were also summarized by severity grade, days of reporting, and injection.

The number and percentage of participants experiencing fever (a temperature greater than or equal to 38.0°C/100.4°F by the oral, axillary, or tympanic route) by severity grade and the number and percentage of participants experiencing a fever of Grade 3 or higher temperature (a temperature greater than or equal to 39.0°C/102.1°F by the oral, axillary, or tympanic route) were summarized.

A 2-sided 95% exact CI using the Clopper-Pearson method was provided for the percentage of participants who reported any solicited local AR, solicited systemic AR, or any solicited AR.

The onset of individual solicited AR was defined as the time point after each injection at which the respective solicited AR first occurred. The number and percentage of participants with onset of individual solicited AR were summarized by study day relative to the corresponding injection (Day 1 through Day 7).

The number of days was calculated as the days that the solicited AR was reported within the 7 days after injection, including the day of injection, regardless of whether it was intermittent or continued. If the solicited AR continued beyond 7 days, the consecutive days a solicited AR was reported after 7 days was included (eg, an event that lasted 5 days in the first 7 days after injection and 3 consecutive days beyond 7 days after injection, the duration was reported as 8 [5 + 3] days).

All solicited ARs that continued beyond 7 days post injection were summarized.

The above analyses of solicited ARs were summarized separately for the following subgroups:

- Age group (< 65 and ≥ 65 years)
- Sex (male, female)
- Baseline SARS-CoV-2 status
- Race and ethnicity

4.2.3.2 Unsolicited TEAEs

Definitions and details regarding AEs are provided in Section 3.7.4.2. Unsolicited AEs were collected for up to 28 days after each IP dose; SAEs, MAAEs, and AEs leading to withdrawal were collected throughout the study.

Unsolicited AEs were coded by SOC and PT according to the MedDRA version 23.0.

All summary tables for unsolicited AEs (except for the overall summary of AEs) were presented by SOC and PT or by PT only for TEAEs with counts of participants included. All safety analyses were summarized by treatment group. Percentages were based upon the number of participants in the Safety Set within each treatment group.

Unsolicited TEAE summaries were provided for TEAEs up to 28 days after any injection and during Part A (Section 4.1.1).

For PTs with at least 7 participants in any treatment group who reported the event, rate ratio, and its 95% CI were provided as a helpful descriptive measure used in review, not a formal method for assessing the statistical significance of the between-group differences in adverse experiences. The rate ratio was calculated as the ratio of percentage of participants reporting the event in mRNA-1273 divided by that in placebo. The 95% CI for rate ratio was provided using the Miettinen and Nurminen method (1985). The threshold of at least 7 participants was chosen because the 95% CI for rate ratio always included one when groups of equal size each had < 7 participants reporting the event, and thus would have added little for review purpose.

The overall summaries of unsolicited TEAEs (number and percentage) by treatment group included the following: any unsolicited TEAEs, any serious TEAEs, any unsolicited TEAEs that were MAAEs, any unsolicited TEAEs leading to discontinuation from participation in the study or study vaccine, any unsolicited severe TEAEs (severity of AEs was assessed as mild, moderate, or severe), and any unsolicited fatal TEAEs. The overviews also included a summary of participants with treatment-related TEAEs in each category.

The following summary tables of TEAEs were provided by SOC and PT using frequency counts and percentages (ie, number and percentage of participants with an event):

- All unsolicited TEAEs
- All treatment-related unsolicited TEAEs
- All SAEs
- All treatment-related SAEs
- All unsolicited TEAEs leading to discontinuation from study vaccine
- All unsolicited TEAEs leading to discontinuation from participation in the study
- All unsolicited severe TEAEs
- All treatment-related unsolicited severe TEAEs
- All unsolicited TEAEs that were MAAEs

All unsolicited TEAEs were summarized by PT, sorting by frequency of the mRNA-1273 group.

A summary of TEAEs by maximum toxicity grade (mild, moderate, and severe) using frequency counts and percentages was provided for all unsolicited TEAEs and all treatment-related unsolicited TEAEs.

The overview of TEAEs and the TEAE summaries presented by SOC and PT were also summarized for the following subgroups: age (< 65 and ≥ 65 years), sex (male, female), and baseline SARS-CoV-2 status. These summaries may have been provided for subgroups of select baseline characteristics.

Separate listings of individual participant AE data were provided for the following: unsolicited TEAEs leading to discontinuation from study vaccine, unsolicited TEAEs leading to discontinuation from participation in the study, SAEs, treatment-related SAEs, and unsolicited treatment-related MAAEs. A listing of deaths including cause of death and a listing of TEAEs in participants who died were provided.

4.2.3.3 Vital Sign Measurements

All vital sign measurement data were presented in a data listing. Values meeting the toxicity grading criteria were flagged. The abnormalities meeting the toxicity grading criteria (Grade 2 or higher) in any vital sign measurement were listed separately. If a participant had a vital sign result of Grade 2 or higher at any post-injection visit, all results of vital sign measurement for that participant were presented in the listing.

Observed values and changes from baseline for all vital sign measurements were summarized at each visit by baseline SARS-CoV-2 serostatus and treatment group. Shift from baseline in the toxicity grades at each visit were summarized by treatment group.

4.2.3.4 Pregnancies

Pregnancies and outcome (if available) were summarized by treatment group and a listing of pregnancies including outcome were provided.

4.2.3.5 Vaccine-Associated Enhanced Respiratory Disease

The DSMB continuously monitored for potential vaccine harm in this study. Potential vaccine harm was assessed based on imbalance between mRNA-1273 versus placebo for both COVID-19 and severe COVID-19 case counts using the Safety Set. For harm monitoring, participants were analyzed according to the IP that they actually received regardless of the group to which they were randomized. For harm monitoring, cases were counted starting after the first dose of study vaccination.

Cases of COVID-19 for the harm monitoring were defined as for the primary efficacy endpoint (eligible symptoms with positive RT-PCR result) but were based on the Safety Set rather than the PP Set. For harm monitoring, cases of COVID-19 were derived based on RT-PCR results and symptoms collected in the clinical database to facilitate continuous monitoring.

Details of harm monitoring are provided in the analysis plan for the DSMB. The monitoring for potential harm based on COVID-19 continued throughout the blinded phase of the study. The DSMB recommended discontinuation of the harm monitoring reports to the DSMB after the DSMB review meeting on 29 Jan 2021.

4.2.4 Immunogenicity Analyses

The secondary immunogenicity endpoints are provided in Section 2. The immunogenicity assessments performed for serum bAb level against SARS-CoV-2 spike protein and bAb level against SARS-CoV-2 N-protein, and serum nAb titer against SARS-CoV-2 are summarized in Section 3.7.3.

The PPRSI was used as the analysis population to characterize immunogenicity of mRNA-1273 (Section 4.1.3).

The following were the immunogenicity assessments (assays) used in this study:

- Serum bAb level against SARS-CoV-2 as measured by ELISA specific to the SARS-CoV-2 S protein (vaccine antigen), including tests for VAC65 spike IgG antibody.
- The MesoScale Discovery-electrochemiluminescence (MSD-ECL) multiplex assay measures bAb to antigens corresponding to S protein, RBD, and N-protein, which is not contained in mRNA-1273. Of note, data on RBD and N-protein by MSD were not available at the time of DBL and thus were not included in this CSR.
- Pseudovirus nAb assay for measuring nAb against SARS-CoV-2 S-pseudotyped viruses pseudovirus nAb ID_{50} and ID_{80} titers (PsVNT50 and PsVNT80).
- WT live virus nAb assay measuring antibody-mediated neutralization of WT live SARS-CoV-2: WT live virus MN50 titers. Of note, data on WT live virus nAb assay were not available at the time of DBL and thus were not included in this CSR.

4.2.4.1 Summary of Antibody-Mediated Immunogenicity Endpoints

Data from quantitative immunogenicity assays outlined in Section 4.2.4 were summarized for each treatment group using positive response rates and geometric means (GMs) with 95% CI at each time point when an assessment was performed. Data from qualitative (ie, yielding a positive or negative result) assays were summarized by tabulating the frequency of positive responses for each assay by treatment group and by baseline SARS-CoV-2 status, if applicable, at each time point that an assessment was performed.

At the time the final blinded efficacy analysis, immunogenicity analyses to characterize immunogenicity of mRNA-1273 were performed. At the time of the immunogenicity analyses, data for bAb to S (MSD, PPD-VAC65) and psVNA ID_{50} and ID_{80} titers were available. The assay by MSD to measure bAb against RBD and N-protein had not yet been validated at the time of the immunogenicity analysis; therefore, these data were not summarized/analyzed. Immunogenicity data at the prespecified time points (Baseline [Day 1], Day 29 [Month 1], and Day 57 [Month 2]) were included.

- The GMT or value with corresponding 95% CI was provided at each time point. The 95% CIs were calculated based on the *t*-distribution of the log-transformed values then back transformed to the original scale for presentation. The following descriptive statistics were also provided at each time point: the number of participants (n), median, minimum, and maximum.

- The geometric mean fold rise (GMFR) with corresponding 95% CI was provided at each post-baseline time point over pre-injection baseline at Day 1. The 95% CIs were calculated based on the *t*-distribution of the log-transformed values then back transformed to the original scale for presentation. The following descriptive statistics were also provided at each time point: the number of participants (n), median, minimum, and maximum.
- Reverse cumulative distribution function curve (RCDF) at each time point. The number and percentage of participants with fold-rise ≥ 2, fold-rise ≥ 3, and fold-rise ≥ 4 from baseline at each post-injection time point were tabulated with 2-sided 95% Clopper-Pearson CIs.
- The Ab assay of interest (bAb to spike (MSD, PPD-VAC65) and PsVNA ID_{50} and ID_{80}) are listed in the table below. For each of them, seroresponse rate was defined as the proportion of participants achieving seroresponse, defined below for each assay/test of interest. Please note that these assay-specific definition of seroresponse was an update of 'seroconversion due to vaccination' used in the protocol and relevant SAP incorporating assay-specific fold-rise criteria based on assay-specific performance characteristics. These assay-specific definitions of seroresponse were documented in a memo (Update on Analysis for Immunogenicity; Appendix 16.1.9) that became available prior to DBL.

Assay Name	Category	Test Name/ Description	Definition of Seroresponse
Pseudovirus (PsVNA)	nAb	PsVNT50 (ID_{50})	baseline <LLOQ: ≥LLOQ baseline ≥LLOQ: 3.3-fold rise
		PsVNT80 (ID_{80})	baseline <LLOQ: ≥LLOQ baseline ≥LLOQ: 2.3-fold rise
Anti-Spike ELISA	bAb	anti-Spike VAC65 Spike IgG Antibody	baseline <LLOQ: ≥LLOQ baseline ≥LLOQ: 4.6-fold rise
MSD multiplex	bAb	anti-Spike	baseline <LLOQ: ≥LLOQ baseline ≥LLOQ: 1.9-fold rise

Abbreviations: bAb = binding antibody; ELISA = enzyme-linked immunosorbent assay; IgG = immunoglobulin G; LLOQ = lower limit of quantitation; MSD = MesoScale Discovery; nAb = neutralizing antibodies; PsVNA = pseudotyped virus neutralization assay; PsVNT50 = 50% pseudotyped lentivirus reporter test; PsVNT80 = 80% pseudotyped lentivirus reporter test.

- Number and proportion of participants achieving seroresponse were provided with 2-sided 95% Clopper-Pearson CIs at each post-baseline time point.

The formula used to calculate GM titer (GMT) and GM level is provided in mRNA-1273-P301 SAP Section 6.7.4 (Appendix 16.1.9).

4.2.4.2 Analysis of Antibody-Mediated Immunogenicity Endpoints

To assess the magnitudes of the differences between the 2 treatment groups (mRNA-1273 vs. placebo) in SARS-CoV-2-specific nAb and S protein-specific bAb, a MMRM using SAS PROC MIXED was used.

For each of the SARS-CoV-2-specific nAb and S protein-specific bAb, the analysis was performed separately for participants whose SARS-CoV-2 status were negative or positive at baseline, respectively. The model included all available log-transformed antibody titers at each post-baseline visit as the dependent variable, treatment groups, visit (as a class variable), and treatment-by-visit interaction visit as fixed effects, with adjustment for stratification factor used for randomization, baseline log-transformed antibody titers if applicable, and participant as a random effect. The model also adjusted for minority group used to sample for the random subcohort. An unstructured covariance structure was used to model the within-participant errors. A Kenward-Roger approximation was used for the denominator degrees of freedom. If there was a convergence issue due to the unstructured covariance matrix, a compound symmetry covariance structure was used to model the within-participant errors. No imputation of missing data was done.

The geometric least squares mean (GLSM) and corresponding 2-sided 95% CI for the antibody titers for each treatment group were provided by visit. The GLSM and corresponding 95% CI results in log-transformed scale estimated from the model were back-transformed to obtain these estimates in the original scale. Geometric mean ratio (GMR), estimated by the ratio of GLSM and the corresponding 2-sided 95% CI, was provided to assess the treatment difference between the mRNA-1273 versus placebo groups at each visit. With each treatment group, within-group comparison of time points may also have been estimated using the same model.

In addition, an analysis of covariance (ANCOVA) model with the treatment group as explanatory variables, adjusting for the stratification factor at randomization, baseline value if applicable, was used to assess the treatment effect at specific time points (scheduled visits) such as Day 57. The GLSM with 95% CI for each treatment group, GMR with 95% CI for treatment difference was estimated from the ANCOVA model. The model also adjusted for minority group used to sample for the random subcohort.

4.2.4.3 Summary of Immunogenicity in COVID-19 Cases on mRNA-1273 With Negative SARS-CoV-2 Status at Baseline

To characterize immunogenicity of mRNA-1273, immunogenicity data (Section 4.2.4) were analyzed using the PPRSI.

It was of interest to examine the immune response in participants on mRNA-1273 with baseline SARS-CoV-2 negative status who were COVID-19 or SARS-CoV-2 infection cases. Immunogenicity data was provided in a subset of baseline SARS-CoV-2 negative participants on mRNA-1273 who were adjudicated COVID-19 cases.

4.3 Changes to the Planned Analyses

The original SAP version 1.0, was dated 08 Sep 2020. The IA and the primary analysis were performed based on SAP version 1.0. The SAP was amended after EUA, version 2.0, dated 08 Mar 2021, and the methods are described herein.

The following were clarifications or additions to the planned analyses from the SAP Version 2.0 (dated 08 Mar 2021):

- Participant discontinuation from the study by month (inclusive of Part A and Part B) was provided.
- Details of the viral load and genotyping analysis methods and results were provided in the Genotyping Report (Appendix 16.5).
- Immunogenicity analyses were performed based on the SAP version 2.0 and a memo entitled “Update on Analysis of Immunogenicity” that provided further clarification and updates on the derivation and analysis (Appendix 16.1.9).
- Available immunogenicity data was provided in mRNA-1273 participants who were adjudicated COVID-19 cases 14 days after the second injection (PP Set).
- Additional safety analyses for AEs of clinical interest were performed by using Standardized MedDRA Queries (SMQs) or Custom MedDRA Queries (CMQs).
- Analyses were performed for secondary efficacy endpoints of SARS-CoV-2 infection regardless of symptomology and severity (all infection) and asymptomatic SARS-CoV-2 infection including results at the PDV.

5 STUDY POPULATIONS

The results in this section are based on the final analysis of Part A based on a database lock of 04 May 2021, unless otherwise specified.

5.1 Disposition of Participants

A total of 30,415 participants were randomly assigned to study treatment: 15,206 participants in the placebo group and 15,209 in the mRNA-1273 group (Figure 5-1 and Table 5-1). A total of 22,882 participants were ≥ 18 and < 65 years and 7,533 were ≥ 65 years.

Overall, treatment compliance was high, with 99.8% of participants receiving the first injection and 96.5% receiving the second injection (Table 5-1).

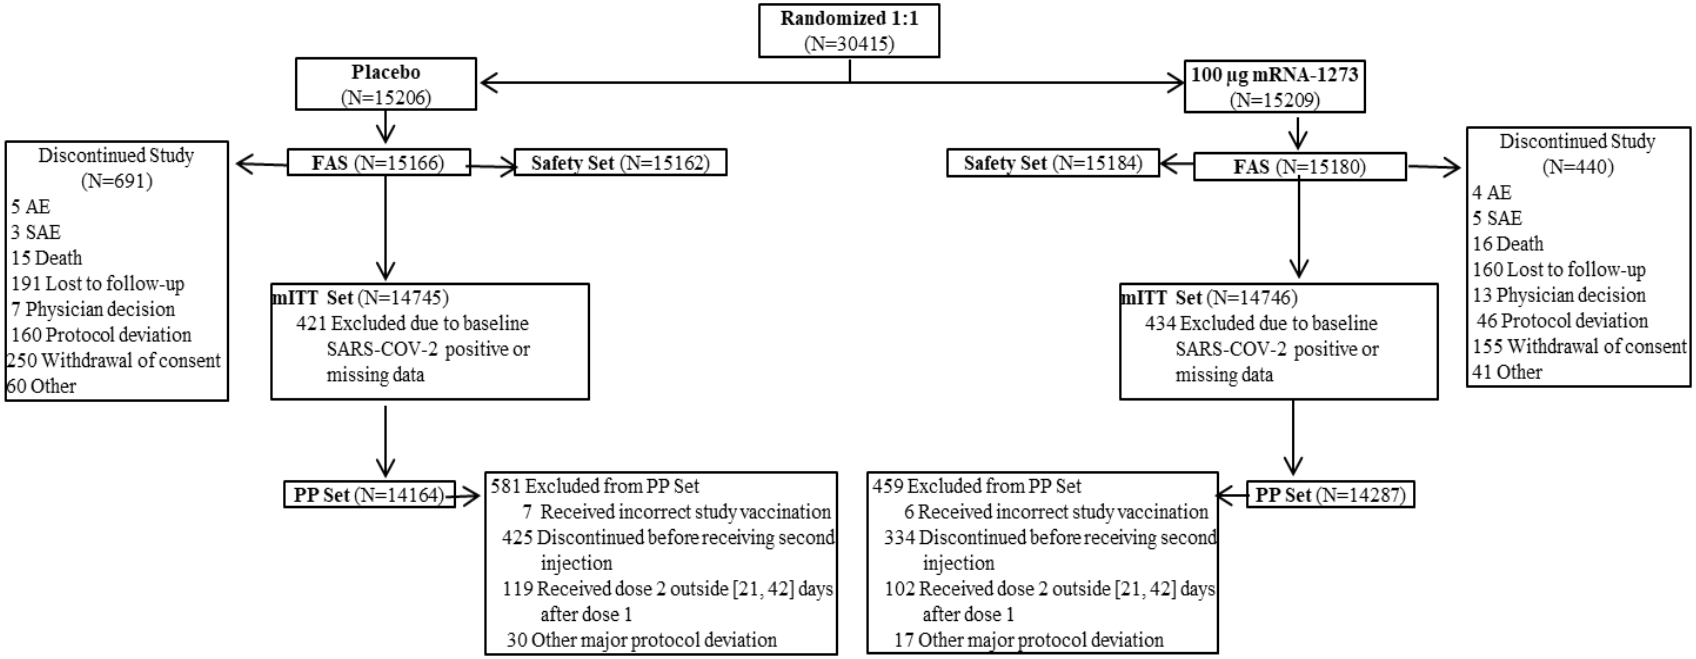
A total of 531 participants (3.5%) who were randomly assigned to receive placebo and 453 participants (3.0%) who were randomly assigned to receive mRNA-1273 discontinued the study vaccine (Table 5-1). The most common reasons for discontinuation of study vaccine were confirmed SARS-CoV-2 infection (ie, diagnosed COVID-19 by detection of SARS-CoV-2 in Day 1 NP swab or COVID-19 diagnosed prior to Day 29), other, and withdrawal of consent by participant.

A total of 691 participants (4.5%) in the placebo group and 440 participants (2.9%) in the mRNA-1273 group discontinued Part A of the study (Table 5-1). The most common reasons for discontinuation from Part A of the study were withdrawal of consent by participant, lost to follow-up, and protocol deviation. A total of 2099 participants (13.8%) in the placebo group and 730 participants (4.8%) in the mRNA-1273 group discontinued the study, Part A and Part B inclusive (Table 14.1.1.1.1.2). Figure 5-2 displays the number of discontinuations by month and shows that the imbalance of discontinuations between the placebo and mRNA-1273 groups coincided with the EUA of the Pfizer-BioNTech COVID-19 vaccine and the Moderna COVID-19 vaccine.

A total of 29,491 participants (14,745 participants in the placebo group; 14,746 participants in the mRNA-1273 group) had a negative SARS-CoV-2 status at baseline, determined by negative RT-PCR test and negative serology test (as measured by Roche Elecsys anti-SARS-CoV-2 assay [Section 4.1.1]) (Table 14.1.1.1.1.1). All of these participants (100%) received the first injection and 28,732 participants (97.4%) received the second injection (14,320 participants [97.1%] in the placebo group; 14,421 participants [97.7%] in the mRNA-1273 group). Among participants with a negative SARS-CoV-2 status at baseline, 425 participants (2.9%) in the placebo group and 334 participants (2.3%) in the mRNA-1273 group discontinued study vaccine. The most common reason for discontinuation of study vaccine in these participants with negative SARS-CoV-2 status at baseline was withdrawal of consent by participant, reported for

102 participants (0.7%) in the placebo group and 73 participants (0.5%) in the mRNA-1273 group.

Figure 5-1: Study Disposition in the Overall Randomized Set in Part A



Abbreviations: AE = adverse event; FAS = full analysis set; mITT = modified intent-to-treat; PP = per-protocol; SAE = serious adverse event.

Percentages are based on the number of randomized subjects.

[a] Subjects are considered to have completed the study if they complete the final visit at Day 759 (Month 25), 24 months following the last injection of investigational product and have no participant decision visit or unblinding date.

5.2 Study Analysis Sets

Overall, the percentage of participants in each analysis set was balanced between the placebo and mRNA-1273 groups, except for the PPRST where larger number of mRNA-1273 recipients were pre-specified to be selected to characterize immunogenicity of mRNA-1273 (Table 5-2).

The Safety Set included all randomized participants who received at least 1 dose of IP (refer to Section 4.1.3 for definitions of each analysis set). The Safety Set was used for all analyses of safety except for the solicited ARs. The Solicited Safety Set included all randomized participants who received at least 1 dose of IP and contributed any solicited AR data; ie, had at least 1 post-baseline solicited safety (eDiary) assessment.

The mITT Set included all participants in the FAS who had no immunologic or virologic evidence of prior COVID-19, ie with negative SARS-CoV-2 status at baseline. A total of 855 participants (421 in the placebo group; 434 in the mRNA-1273 group) had a positive or missing baseline SARS-CoV-2 status and were excluded from the mITT Set (Table 14.1.2.4).

Table 5-3 provides a summary of positive, negative, and missing of RT-PCR test and Elecsys results at baseline.

The primary efficacy analysis was based on the PP Set, which included all participants in the mITT Set who received planned doses of IP per schedule and had no major protocol deviations impacting critical or key study data. A total of 1040 participants (3.4%) including 581 participants (3.8%) in the placebo group and 459 participants (3.0%) in the mRNA-1273 group were excluded from the PP Set (Table 14.1.2.4). The most common reason for exclusion from the PP Set was participant discontinued study or study vaccination before receiving second injection (425 participants [2.8%] in the placebo group and 334 participants [2.2%] in the mRNA-1273 group). Other reasons for exclusion included participant received second injection out of window (-7/+14 days) for the PP Set (221 participants [0.7%]), received incorrect study vaccination (13 participants [< 0.1%]), and other major protocol deviation impacting critical data (47 participants [0.2%]).

A total of 29,491 participants (14,745 in the placebo group; 14,746 in the mRNA-1273 group) had a negative SARS-CoV-2 status at baseline, determined by negative RT-PCR test and negative serology test (as measured by Roche Elecsys anti-SARS-CoV-2 assay) (Table 14.1.2.1). A total of 684 participants (337 in the placebo group; 347 in the mRNA-1273 group) had a positive SARS-CoV-2 status at baseline.

The PPRST is described in Section 6.5.

5.3 Predefined Quality Tolerance Limits Assessments

As of the database lock (04 May 2021), there have been no excursions from the PDQTLs. The team is continuing to monitor them per the plan (Section 3.8.5), and the final results will be presented in the EOS CSR.

5.4 Major Protocol Deviations

Major protocol deviations were defined as a subset of protocol deviations that could have significantly impacted the completeness, accuracy, or reliability of the study data or that may have significantly affected a participant's rights, safety, or well-being. Major protocol deviations were determined and documented by the Sponsor prior to database lock and unblinding.

Select major protocol deviations that impacted critical or key study data, and participants with such deviations were excluded from the PP Set (see Section 5.2 for exclusions from PP Set).

The most common (≥ 2% of participants) major protocol deviations in the Randomization Set were missing endpoint assessments (15.1% total; 16.3% placebo, 13.9% mRNA-1273), ICF process/timing (7.3% total; 7.4% placebo, 7.3% mRNA-1273), study treatment administration/dispensing (5.5% total; 7.3% placebo, 3.6% mRNA-1273), visit scheduling (5.5%

total; 5.9% placebo, 5.2% mRNA-1273), study procedures/assessments (4.8% total; 6.1% placebo, 3.5% mRNA-1273), and study treatment randomization (3.8% total; 4.0% placebo, 3.7% mRNA-1273) (Table 5-4).

Major protocol deviations related to concomitant medication were reported for 1.0% of participants (1.2% in the placebo group; 0.9% in the mRNA-1273 group) (Table 5-4). Concomitant vaccine use is discussed in Section 5.7.

Section 5.2 discusses reasons for exclusion from the PP Set and Table 14.1.2.4 provides a summary of reasons for exclusion from the PP Set.

Table 5-4: Major Protocol Deviations (Randomization Set)

Deviation Type	Placebo (N=15206) n (%)	mRNA-1273 (N=15209) n (%)	Total (N=30415) n (%)

Visit scheduling	897 (5.9)	786 (5.2)	1683 (5.5)
Withdrawal/term criteria	3 (<0.1)	2 (<0.1)	5 (<0.1)

A subject is counted once if the subject had multiple protocol deviations within one protocol deviation type.
Source: Table 14.1.1.6.

5.5 Demographics and Other Baseline Characteristics

Overall, in the FAS, participant demographics and baseline characteristics were similar between the groups (Table 5-5). A slightly higher proportion of males versus females (52.6% versus 47.4%. respectively) were enrolled. The mean age at screening was 51.4 years (range: 18 to 95 years); 75.2% of participants were ≥ 18 to < 65 years of age and 24.8% were ≥ 65 years. The majority of participants were White (79.2%) and not Hispanic or Latino (78.6%). Communities of color comprised 37.2% of the study population; the racial and ethnicity proportions observed in this study were generally representative of US demographics.

The study planned to enroll at least 25% and up to 50% of participants most at risk for severe complications of COVID-19, including those ≥ 65 years of age or < 65 years of age with

co-morbid medical conditions such as diabetes (Type 1, Type 2, or gestational), significant cardiac disease, chronic pulmonary disease, severe obesity, liver disease, and HIV infection. The study enrolled a total of 41.5% of participants who were considered at risk for severe COVID-19 (16.7% participants who were < 65 years and at risk, and 24.8% participants who were ≥ 65 years), indicating that enrollment goals were met (Table 5-5).

Overall, the majority of participants (82.5%) had a specified occupational risk for acquisition of SARS-CoV-2 infection; the most common occupational risks included other (31.9%) and health care workers (25.2%) (Table 5-5). A total of 83.8% of participants had a location or living circumstances risk for acquisition of SARS-CoV-2.

Participant demographics and baseline characteristics in the mITT Set and PP Set were similar to those in the FAS (Table 14.1.3.3.2 and Table 14.1.3.4.2).

Participants who received only one injection of IP had a mean age at screening of 47 years (range, 18 to 90 years) (Table 14.1.3.3.4). Minorities, defined as Blacks or African Americans, Hispanics or Latinos, American Indians or Alaska Natives, Native Hawaiians or other Pacific Islanders comprised 47.3% of participants who received only one injection. A total of 33.4% of participants who received only one injection were considered at risk for severe COVID-19 (16.5% participants who were < 65 years and at risk, and 16.9% participants who were > 65 years).

Abbreviations: IRT = interactive response technology; Max = maximum; Min = minimum; RT-PCR = reverse transcription polymerase chain reaction; SD = standard deviation.

Percentages are based on the number of subjects in Full Analysis Set.

[a] Based on stratification factor from IRT, subjects who are < 65 years old are categorized as at risk for severe COVID-19 illness if they have at least 1 of the risk factors specified in the study protocol at Screening.

[b] Subjects could be under one or more categories, and are counted once at each category.

[c] Age and health risk for severe COVID-19 are derived from age and risk factors collected on case report form (CRF).

[d] Baseline SARS-CoV-2 Status: Positive if there is immunologic or virologic evidence of prior COVID-19, defined as positive RT-PCR test or positive Elecsys result at Day 1. Negative is defined as negative RT-PCR test and negative Elecsys result at Day 1.

[e] Minority is defined as: Blacks or African Americans, Hispanics or Latinos, American Indians or Alaska Natives, Native Hawaiians, and other Pacific Islanders, and Non-Minority includes all the others whose race or ethnicity is not unknown, unreported or missing.

	>=18 and <65 Years			>=65 Years			Overall		
	Placebo (N=11413)	**mRNA-1273 (N=11413)**	**Total (N=22826)**	**Placebo (N=3753)**	**mRNA-1273 (N=3767)**	**Total (N=7520)**	**Placebo (N=15166)**	**mRNA-1273 (N=15180)**	**Total (N=30346)**

[f] White is defined as White and non-Hispanic, and Communities of Color includes all the others whose race or ethnicity is not unknown, unreported or missing.

Source: Table 14.1.3.1.2.

5.6 Medical History

The incidence of participants with any medical history was balanced between the placebo and mRNA-1273 groups (Table 5-6). The most frequently reported medical history conditions were hypertension (29.7% in the placebo group; 29.3% in the mRNA-1273 group), seasonal allergy (27.5% in the placebo group; 27.6% in the mRNA-1273 group), postmenopause (14.8% in the placebo group; 15.6% in the mRNA-1273 group), and gastroesophageal reflux disease (14.6% in the placebo group; 15.3% in the mRNA-1273 group) (Table 14.1.4.1). Among the other most common medical history conditions (≥ 10% and < 15% of participants in either group) were drug hypersensitivity, depression, anxiety, hyperlipidemia, and osteoarthritis.

Participants with a medical history of autoimmune disorder, angioedema, anaphylaxis, hypersensitivity, or dermal fillers were not excluded from the study (Table 5-6). In the mRNA-1273 group, 1152 participants (7.6%) had a history of autoimmune disorder and 3064 participants (20.2%) had a history of hypersensitivity.

Table 5-6: Summary of Medical History (Safety Set)

	Placebo (N=15162) n (%)	mRNA-1273 (N=15184) n (%)	Total (N=30346) n (%)
Number of subjects with any medical history	13954 (92.0)	13999 (92.2)	27953 (92.1)
Number of subjects with at least one autoimmune disorder	1144 (7.5)	1152 (7.6)	2296 (7.6)
Number of subjects with at least one angioedema event	98 (0.6)	100 (0.7)	198 (0.7)
Number of subjects with at least one anaphylaxis event	27 (0.2)	23 (0.2)	50 (0.2)
Number of subjects with at least one hypersensitivity event	3045 (20.1)	3064 (20.2)	6109 (20.1)
Number of subjects with at least one dermal fillers event	15 (<0.1)	16 (0.1)	31 (0.1)

Note: At each level of subject summarization, a subject is counted once if the subject reported one or more findings.
MedDRA version 23.0.
Source: Table 14.1.4.1, Table 14.1.4.4, Table 14.1.4.5, Table 14.1.4.6, Table 14.1.4.7, and Table 14.1.4.8.

5.7 Prior and Concomitant Medications

Overall, concomitant medications and/or non-study vaccination throughout the study was reported for 62.3% of participants; 52.1% of participants in the placebo group and 72.5% of participants in the mRNA-1273 group (Table 14.1.5.1.1). The imbalance generally appears to be driven by antipyretic or analgesic medication use in the mRNA-1273 group during the study. A higher proportion of participants in the mRNA-1273 group (60.0%) reported any concomitant medications or non-study vaccination within 7 days post injection than participants in the placebo group (25.4%). An imbalance was also observed within 14 days post injection (62.8% in the mRNA-1273 group vs. 31.0% in the placebo group) and within 28 days post injection (72.3% vs. 51.7%, respectively).

Concomitant vaccine use throughout the study was reported for 23.5% of participants, with no notable differences between the placebo and mRNA-1273 groups (Table 14.1.5.4.1). Concomitant vaccine use within 7 days, 14 day, and 28 days post injection was reported for 0.5%, 1.7%, and 23.4% of participants, respectively, with no notable differences between the placebo and mRNA-1273 groups.

Influenza vaccine was the most frequently reported concomitant vaccine, with no notable differences between the placebo and mRNA-1273 groups (Table 14.1.5.4.2). Seasonal influenza vaccine within 14 days post injection and within 28 days post injection was reported for a total of 1.5% and 23.1% participants, respectively (Table 14.1.5.1.1). No notable differences were observed between the placebo and mRNA-1273 groups.

5.8 Exposure and Compliance

Compliance with dosing scheduling in the Randomized Set was high and is discussed in Section 5.1. In the PP Set, a total of 28,451 participants received the first and second injection (14,164 in the placebo group; 14,287 in the mRNA-1273 group) (Table 14.1.6.6.3 and Table 14.1.6.5.3).

A total of 13 participants (7 participants in the placebo group; 6 participants in the mRNA-1273 group) received incorrect study vaccination and were excluded from the PP Set (Section 5.2)

5.9 Duration of Follow-Up

The data cutoff date for DBL was 26 Mar 2021. The time on study, or duration of follow-up from randomization, is defined as the time from randomization to death/discontinuation from study, or 26 Mar 2021, whichever occurs earlier.

The median duration of follow-up after randomization for the entire period up to the data cutoff for DBL (inclusive of Part A and Part B) was 212 days (range, 1 to 243 days) (Table 5-7). The

median duration of follow-up from randomization to PDV (ie, Part A) for participants who had a PDV before the data cutoff date was 148 days (range, 30 to 241 days). The median duration of follow-up after second injection (in participants who received the second injection) for the entire period up to the data cutoff for DBL (inclusive of Part A and Part B) was approximately 6 months; 183 days (range, 1 to 218 days).

For the 2 age groups, the median duration of follow-up after randomization for the entire period up to the data cutoff for DBL (inclusive of Part A and Part B) was 211 days in participants ≥ 18 to < 65 years and 214 days in participants ≥ 65 years (Table 14.1.6.2.3). The median duration of follow-up from randomization to PDV (ie, Part A) for participants who had a PDV on or before the data cutoff date was 148 days (range, 31 to 241 days) in participants ≥ 18 to < 65 years and 147 days (range, 30 to 234 days) in participants ≥ 65 years. The median duration of follow-up after second injection (in participants who received the second injection) for the entire period up to the data cutoff for DBL (inclusive of Part A and Part B) was approximately 6 months in both age groups; 180 days (range, 1 to 218 days) in participants ≥ 18 to < 65 years and 185 days (range 8 to 218 days) in participants ≥ 65 years. In participants ≥ 18 to < 65 years, a total of 44.6% had at least 6 months of follow-up after the second injection (47.3% in the mRNA-1273 group; 42.0% in the placebo group). In participants ≥ 65 years, a total of 54.4% had at least 6 months of follow-up after the second injection (55.8% in the mRNA-1273 group; 52.9% in the placebo group).

To enhance the diversity of the trial population, an effort was made to increase enrollment in communities of color. This effort increased toward the end of the enrollment period and resulted in a slightly reduced study duration for communities of color. Across communities of color, the median study duration from second injection in participants who received the second injection was approximately 5.5 months (169 days in Black or African Americans, 165 days in Asians, 169.5 days in American Indian or Alaska Natives, 169 days in Native Hawaiian or other Pacific Islanders, and 171 days in those identified as multiple race) compared with approximately 6.2 months (185 days) for White participants (Table 14.1.6.2.5). Median study duration from second injection in subjects who received the second injection was generally balanced between the placebo and mRNA-1273 groups within all race groups.

In Hispanic or Latino participants, the median study duration from second injection in participants who received the second injection was 170 days (Table 14.1.6.2.6). In participants who were not Hispanic or Latino, the median study duration from second injection in participants who received the second injection was 185 days. Median study duration from second injection in subjects who received the second injection was balanced between the placebo and mRNA-1273 groups within these ethnicity subgroups.

Table 5-7: Summary of Study Duration (Safety Set)

	Placebo (N=15162)	mRNA-1273 (N=15184)	Total (N=30346)

6 EFFICACY RESULTS

6.1 Efficacy Results for Primary Endpoint

The primary efficacy endpoint was VE of mRNA-1273 to prevent the first occurrence of adjudicated COVID-19 starting 14 days after the second injection of IP in the PP Set. Vaccine efficacy was assessed at 3 different timepoints – an IA based on a data snapshot on 11 Nov 2020, the primary analysis based on a data snapshot on 25 Nov 2020, and the final analysis of Part A based on database lock of 04 May 2021.

6.1.1 Interim Analysis (11 Nov 2020) and Primary Efficacy Analysis (25 Nov 2020)

The IA of efficacy (11 Nov 2020) demonstrated formal study success based on 95 cases: the VE point estimate (95% CI) based on the hazard ratio was 94.5% (86.5, 97.8); $p < 0.0001$ (Table 6-1). The primary efficacy analysis (25 Nov 2020), which was performed on 196 COVID-19 cases, confirmed the result of the IA: the VE point estimate (95% CI) based on the hazard ratio was 94.1% (89.3%, 96.8%; $p < 0.0001$).

Source tables supporting the results of the primary endpoint for the interim and the primary efficacy analyses are provided in Section 14.2.1 and Section 14.2.2, respectively. Additional analyses of these data have been previously submitted to the applicable regulatory agencies supporting conditional use of mRNA-1273.

Table 6-1: Interim and Primary Analysis of Vaccine Efficacy of mRNA-1273 to Prevent COVID-19* Based on Adjudication Committee Assessments Starting 14 Days After Second Injection (Per-Protocol Set; 11 Nov 2020 and 25 Nov 2020 Data Snapshots)

	Interim Analysis (11 Nov 2020)[a]		Primary Analysis (25 Nov 2020)	
	mRNA-1273 (N=13934)	Placebo (N=13883)	mRNA-1273 (N=14134)	Placebo (N=14073)
Number of participants with COVID-19, n (%)	5 (< 0.1)	90 (0.6)	11 (< 0.1)	185 (1.3)
Vaccine efficacy based on hazard ratio (95% CI)[b]	0.945 (0.865, 0.978)		0.941 (0.893, 0.968)	
p-value[c]	<.0001		<.0001	
Person-years[d]	2716.9	2697.5	3304.9	3273.7
Incidence rate per 1,000 person-years (95% CI)[e]	1.840 (0.598, 4.295)	33.365 (26.829, 41.011)	3.328 (1.662, 5.955)	56.510 (48.660, 65.266)
Vaccine efficacy based on incidence rate (95% CI)[f]	0.945 (0.87, 0.98)		0.941 (0.892, 0.971)	

Abbreviations: CI = confidence intervals.

[a] EUA submission (interim efficacy analysis)

[b] Vaccine efficacy is defined as 1 – hazard ratio (mRNA-1273 vs. placebo), and 95% CI was estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor.

[c] One-sided p-value from stratified Cox proportional hazard model to test the null hypothesis VE ≤ 0.3.

[d] Person-years is defined as the total years from randomization date to the date of COVID-19, last date of study participation, or efficacy data cutoff date, whichever is earlier.

[e] Incidence rate is defined as the number of participants with an event divided by the number of participants at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI was calculated using the exact method (Poisson distribution) and adjusted by person-years.

[f] Vaccine efficacy is defined as 1 – ratio of incidence rate (mRNA-1273 vs placebo). The 95% CI of the ratio was calculated using the exact method conditional upon the total number of cases, adjusting for person-years.

Source: Table 14.2.2.1.1.1.1 (11 Nov 2020) and Table 14.2.2.1.1.1.1 (25 Nov 2020)

6.1.2 Final Efficacy Analysis (04 May 2021)

The final efficacy analysis of the primary endpoint for Part A (04 May 2021) was performed on 799 adjudicated first occurrences of COVID-19 starting at least 14 days after the second injection in the PP Set (Table 6-2).

The follow-up period for the final blinded efficacy analysis provided a median of 148 days (approximately 5.3 months, where 1 month = 28 days) from randomization to the PDV for participants who completed their PDV on or before the data cut-off date (Table 14.1.6.2.1). Additionally, the median duration of follow-up from the PDV to the data cutoff was 67 days, during which time blinded follow-up continued for participants who did not complete their PDV on or before to the data cut-off. Together, these provide a total follow-up duration of approximately 7.6 months from randomization (or approximately 6.5 months from the second injection). Additional COVID-19 case information for the median 67-day period from PDV to data cutoff date will be provided in a Part B addendum to this CSR.

The results of this analysis were consistent with the results of the interim and primary efficacy analyses (Section 6.1.1), confirming persistent, high efficacy over a substantially larger case database and over the median 5.3-month blinded observation period of Part A. For the final efficacy analysis, the VE point estimate (95% CI) was 93.2% (91.0%, 94.8%; $p < 0.0001$) and the 95% CI was observed to be within the 95% CIs for the interim and primary efficacy analyses.

Table 6-2: Final Part A Analysis of Vaccine Efficacy of mRNA-1273 to Prevent COVID-19* Based on Adjudication Committee Assessments Starting 14 Days After Second Injection (Per-Protocol Set; 04 May 2021 Database Lock)

	Placebo (N=14164)	mRNA-1273 (N=14287)
Number of subjects with COVID-19*, n (%)	744 (5.3)	55 (0.4)
Number of subjects censored, n (%)	13420 (94.7)	14232 (99.6)
Vaccine efficacy based on hazard ratio (95% CI) [a]		0.932 (0.910, 0.948)
p-value [b]		<.0001
Person-years [c]	5445.2	5729.9
Incidence rate per 1,000 person-years (95% CI) [d]	136.633 (126.991, 146.814)	9.599 (7.231, 12.494)
Vaccine efficacy based on incidence rate (95% CI) [e]		0.930 (0.908, 0.948)

Abbreviations: CI = confidence intervals; RT-PCR = reverse transcription polymerase chain reaction.

* With the censoring rules for efficacy analyses. COVID-19 case is based on eligible symptoms and positive RT-PCR within 14 days. If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys.

[a] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor.

[b] 1-sided p-value from stratified Cox proportional hazard model to test the null hypothesis VE <= 0.3.

[c] Person-years is defined as the total years from randomization date to the date of COVID-19, the date of earliest positive RT-PCR or Elecsys at scheduled visits, last date of study participation, or efficacy data cutoff date, whichever is earlier.

[d] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

[e] VE is defined as 1 – ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years.

Source: Table 14.2.2.1.3.1.1.

6.1.2.1 Sensitivity Analysis Results for Final Blinded Efficacy

As a sensitivity analysis, VE of mRNA-1273 to prevent COVID-19 was analyzed and COVID-19 incidence rates were estimated in the mITT Set, which includes participants in the Randomization Set who had no evidence of prior SARS-CoV-2 infection and who received at least 1 dose of study IP. The mITT Set provides a more conservative estimate of VE of mRNA-1273 and incidence rates than the PP Set by including participants who may have received only 1 dose of IP or who might have had a major protocol deviation, thereby including a

broader population than the PP Set (refer to Section 4.1.3 for the definitions of the analysis sets). Results were consistent with those observed for the PP Set (VE point estimate [95% CI] based on the hazard ratio was 92.8% [90.6%, 94.5%]; Table 14.2.2.1.3.1.2).

Table 6-3 presents adjudicated COVID-19 cases after randomization by time period in the mITT Set, and it is apparent that the number of cases starts to diverge between placebo and mRNA-1273 groups in the time period from randomization up to 14 days after the first injection.

Table 6-3: Summary of COVID-19* Based on Adjudication Committee Assessments Starting After Randomization by Time Period (mITT Set)

	Placebo (N=14745)	mRNA-1273 (N=14746)
Number of subjects with COVID-19*, n (%)	834 (5.7)	69 (0.5)
Number of events		
From randomization up to 14 days after first injection	11	6
>=14 up to 21 days after first injection	7	1
>=21 days after first injection up to second injection	41	3
From second injection up to 7 days after second injection	11	1
>=7 up to 14 days after second injection	13	0
>=14 up to 28 days after second injection	49	4
>=28 up to 56 days after second injection	181	16
>=56 up to 84 days after second injection	230	13
>=84 up to 112 days after second injection	207	17
>=112 days after second injection	84	8

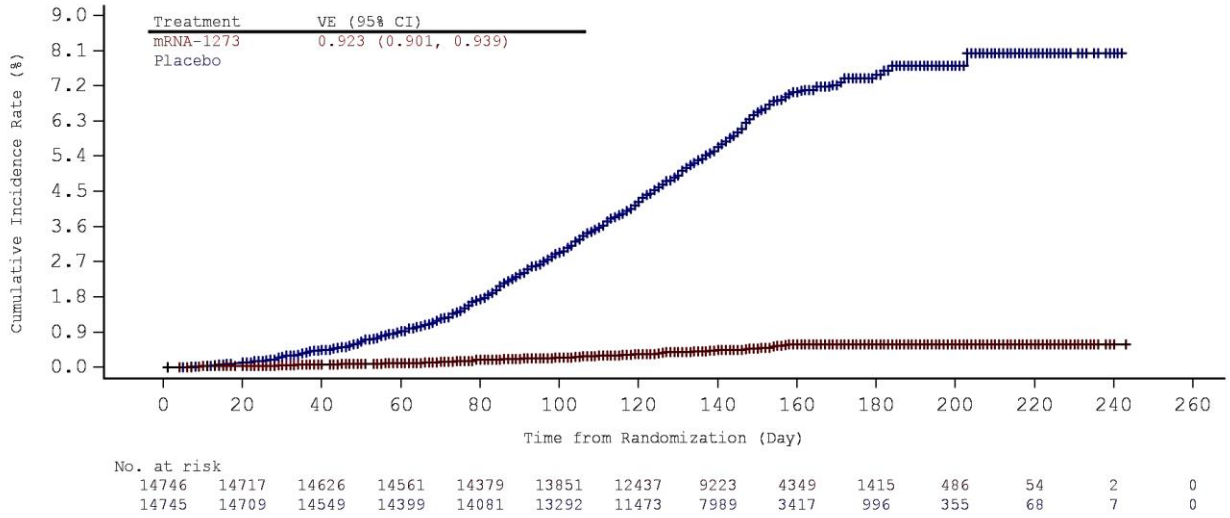
Abbreviations: RT-PCR = reverse transcription polymerase chain reaction.

* With the censoring rules for efficacy analyses. COVID-19 case is based on eligible symptoms and positive RT PCR within 14 days. If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys.

Source: Table 14.2.1.1.2.1.3.4.

The cumulative incidence rate curves for adjudicated COVID-19 cases starting after randomization in the mITT Set (Figure 6-1) present a consistent picture, indicating early onset of protection. Thereafter, for the remainder of the observation period for Part A, the cumulative incidence rate for the placebo group increased steadily while it remained stable and low in the mRNA-1273 group (Table 14.2.1.1.2.1.5.2).

Figure 6-1: Cumulative Incidence Rate Curves of COVID-19* Based on Adjudication Committee Assessments Starting After Randomization (mITT Set; 04 May 2021 Database Lock)



Abbreviations: CI = confidence interval.

* With the censoring rules for efficacy analyses. COVID-19 case is based on eligible symptoms and positive RT-PCR within 14 days. If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms within 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys.

Vaccine efficacy (VE) is defined as 1 – hazard ratio (mRNA-1273 vs. placebo) and 95% CI was estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor.

Source: Figure 14.2.2.1.3.1.4.

The sensitivity analysis of the primary endpoint in the PP Set using different starting days for counting adjudicated cases of COVID-19 was performed for the following time points: after the second injection (Table 14.2.2.1.3.2.1), 14 days after the first injection (Table 14.2.2.1.3.3.1), and after randomization (Table 14.2.2.1.3.5.1). The results of these analyses were consistent with those of the primary analysis starting 14 days after the second injection. The VE of mRNA-1273 to prevent COVID-19 starting 14 days after the first injection was also a secondary objective and results are detailed in Section 6.2.3.

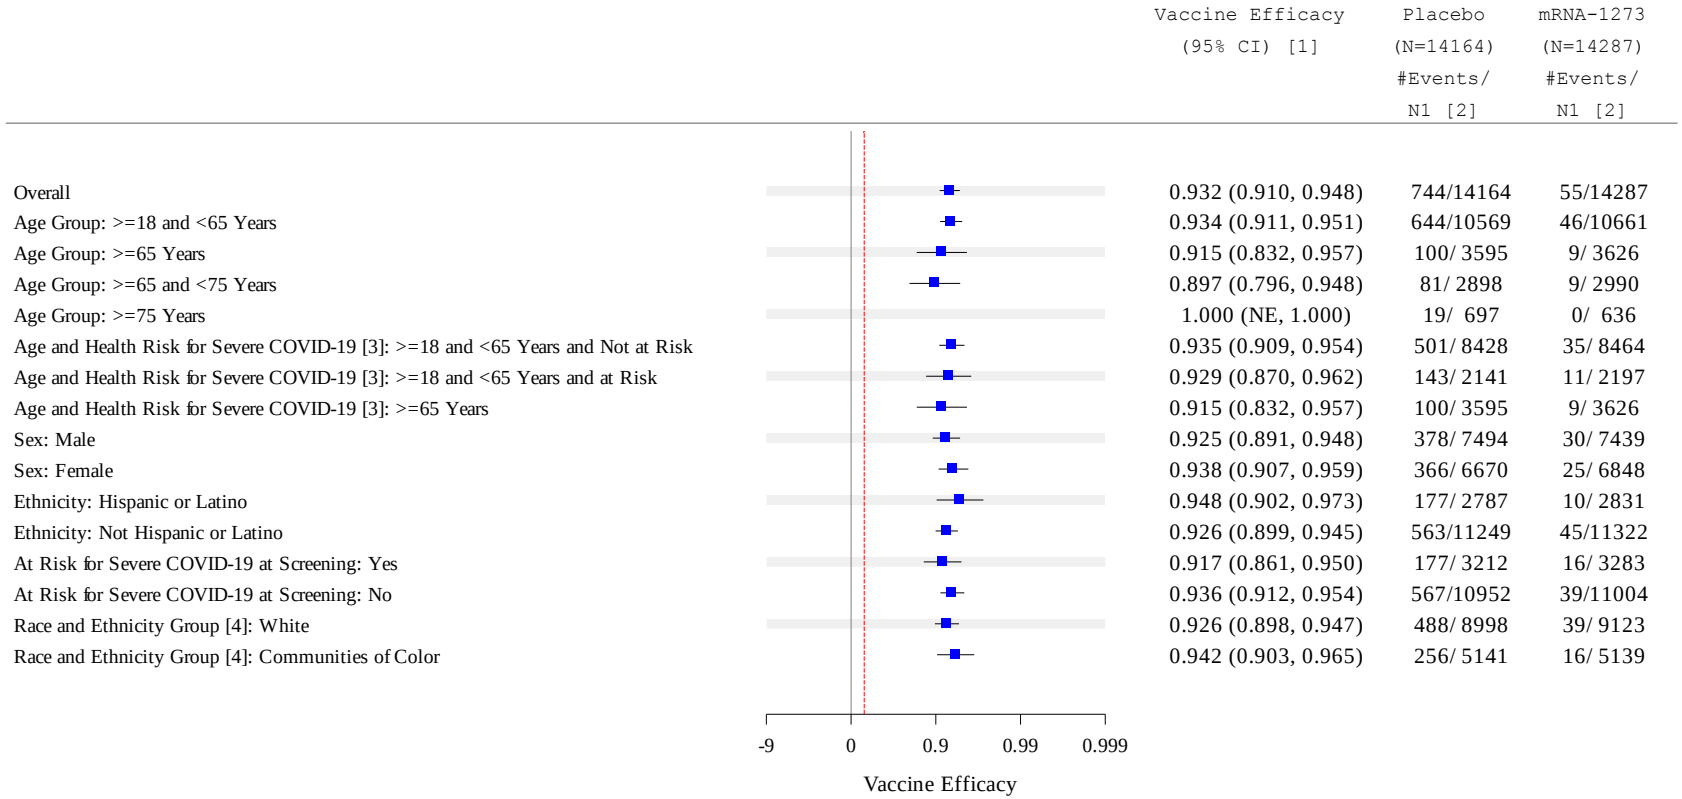
A summary of adjudicated COVID-19 cases by time period after randomization for the PP Set is provided in Table 14.2.1.1.2.1.3.1

Additional analyses were performed on the primary efficacy endpoint without adjudication; these results are presented in Section 14.2.3.

6.1.2.2 Subgroup Analysis Results for Final Blinded Efficacy

The observed efficacy in each subgroup was consistent with the high efficacy observed for the primary endpoint across the entire population, and the lower bound of the 95% CI of the individual subgroup analyses exceeded 30%, one of the success criteria for the interim efficacy analysis. A Forest Plot of subgroup analyses of VE of mRNA-1273 to prevent adjudicated COVID-19 cases starting 14 days after the second injection in the PP Set is presented in Figure 6-2. Results were consistent across subgroups (VE point estimates within the 95% CI for the overall dataset) stratified by age groups (≥ 18 to < 65 years, ≥ 65 years, ≥ 65 years to < 75 years, and ≥ 75 years); age and health risk (≥ 18 to < 65 years and not at risk, ≥ 18 to < 65 years and at risk, and ≥ 65 years), sex (male and female), ethnicity (Hispanic or Latino and not Hispanic or Latino); presence of risk for severe COVID-19 at screening; and race and ethnicity. With respect to the subgroup analysis for race and ethnicity, limited numbers of participants in each ethnic group contributed to the primary efficacy endpoint. Therefore, the race and ethnicity data were pooled into a “communities of color” group for this analysis to ensure that the subpopulations in the study would be large enough for meaningful analysis. Tables of COVID-19 case incidence and VE of mRNA-1273 for each individual race and ethnicity are presented in Section 14.2.3.

Figure 6-2: Forest Plot of Subgroup Analysis of Vaccine Efficacy of mRNA-1273 to Prevent COVID-19* Based on Adjudication Committee Assessments Starting 14 Days After Second Injection (Per-Protocol Set; 04 May 2021 Database Lock)



Note: The dotted red reference line indicates vaccine efficacy of 0.3, the acceptable lower bound for the 95% CI of the primary endpoint for the interim efficacy analysis.

* With the censoring rules for efficacy analyses. COVID-19 case is based on eligible symptoms and positive RT-PCR within 14 days. If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms within 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys.

[1] Vaccine efficacy, defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor if applicable.

[2] Based on the number of subjects in each subgroup.

[3] Age and health risk for severe COVID-19 are derived from age and risk factor collected on case report form (CRF).

[4] White is defined as White and non-Hispanic, and Communities of Color includes all the others whose race or ethnicity is not unknown, unreported or missing.

Source: Figure 14.2.2.1.3.2.3.

6.2 Efficacy Results for Secondary Endpoints

The observed efficacy for each secondary endpoint was consistent with the high efficacy observed for the primary endpoint: the VE with 95% CI is reported for each secondary endpoint. The results in this section are from the final analysis of Part A based on a database lock of 04 May 2021, unless otherwise indicated.

6.2.1 Severe COVID-19

The VE of mRNA-1273 to prevent adjudicated severe COVID-19 cases starting 14 days after second injection was consistent with the VE for the primary endpoint and was numerically higher.

In the final analysis of efficacy, 108 participants had adjudicated severe COVID-19 starting 14 days after second injection in the PP Set (106 cases in the placebo group and 2 cases in the mRNA-1273 group); the VE point estimate (95% CI) based on the hazard ratio was 98.2% (92.8%, 99.6%; Table 6-4), confirming and extending the findings of the primary analysis of 25 Nov 2020 based on a median of 148 days (final analysis) versus 78 days (primary analysis) of efficacy follow-up after randomization. Among these participants, 3 deaths in the placebo group were attributed to COVID-19 (Section 6.2.5).

Additional analyses were performed based on eligible symptoms for severe COVID-19 and positive RT-PCR without adjudication; the results were similar to those based on adjudicated cases and are presented in Section 14.2.3.

Table 6-4: Analysis of Vaccine Efficacy of mRNA-1273 to Prevent Severe COVID-19* Based on Adjudication Committee Assessments Starting 14 Days After the Second Injection (Per-Protocol Set)

	Placebo (N=14164)	mRNA-1273 (N=14287)
Number of subjects with severe COVID-19*, n (%)	106 (0.7)	2 (<0.1)
Number of subjects censored, n (%)	14058 (99.3)	14285 (>99.9)
Vaccine efficacy based on hazard ratio (95% CI) [a]		0.982 (0.928, 0.996)
Person-years [b]	5546.2	5737.9
Incidence rate per 1,000 person-years (95% CI) [c]	19.112 (15.648, 23.116)	0.349 (0.042, 1.259)
Vaccine efficacy based on incidence rate (95% CI) [d]		0.982 (0.932, 0.998)

Abbreviations: CI = confidence intervals; RT-PCR = reverse transcription polymerase chain reaction.

* With the censoring rules for efficacy analyses. COVID-19 case is based on eligible symptoms and positive RT-PCR within 14 days. If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys. Severe COVID-19 case is defined based on COVID-19 case.

[a] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor.

[b] Person-years is defined as the total years from randomization date to the date of severe COVID-19, the date of earliest positive RT-PCR or Elecsys at scheduled visits, last date of study participation, or efficacy data cutoff date, whichever is earlier.

[c] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

[d] VE is defined as 1 – ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years.

Source: Table 14.2.2.2.3.1.1.

Table 6-5 presents adjudicated severe COVID-19 cases after randomization by time period in the PP Set, and it is apparent that the number of cases starts to diverge between placebo and mRNA-1273 groups in the time period of 7 to 14 days after the second injection.

Table 6-5: Summary of Severe COVID-19* Based on Adjudication Committee Assessments Starting After Randomization by Time Period (Per-Protocol Set)

	Placebo (N=14164)	mRNA-1273 (N=14287)
Number of subjects with severe COVID-19*, n (%)	107 (0.8)	2 (<0.1)
Number of events		
From randomization up to 14 days after first injection	0	0
>=14 up to 21 days after first injection	0	0
>=21 days after first injection up to second injection	0	0
From second injection up to 7 days after second injection	0	0
>=7 up to 14 days after second injection	1	0
>=14 up to 28 days after second injection	7	0
>=28 up to 56 days after second injection	25	0
>=56 up to 84 days after second injection	33	2
>=84 up to 112 days after second injection	28	0
>=112 days after second injection	13	0

Abbreviations: RT-PCR = reverse transcription polymerase chain reaction.

* With the censoring rules for efficacy analyses. COVID-19 case is based on eligible symptoms and positive RT-PCR within 14 days. If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys. Severe COVID-19 case is defined based on COVID-19 case.

Source: Table 14.2.1.1.2.2.3.1.

Similar results were noted for the sensitivity analysis, based on the mITT Set, of adjudicated severe COVID-19 starting 14 days after the second injection (VE point estimate [95% CI] based on the hazard ratio was 98.2% [92.8%, 99.6%]; Table 14.2.2.2.3.1.2). Sensitivity analyses using different starting days were performed for counting adjudicated severe COVID-19 cases starting after second injection, 14 days after first injection, and after randomization; these results are presented in Section 14.2.3.

An exploratory analysis of VE of mRNA-1273 to prevent severe COVID-19 starting 14 days after the first injection was carried out for participants in the mITT Set who received only 1 injection, and the results are provided in Table 14.2.2.2.4.3.2.

Subgroup analyses of VE of mRNA-1273 to prevent adjudicated severe COVID-19 were performed and the observed efficacy in each subgroup was consistent with the high efficacy observed across all cases of adjudicated severe COVID-19. Since there were only 2 cases of

adjudicated severe COVID-19 in the mRNA-1273 group, the subgroup analyses were not very informative beyond the consistently high efficacy.

The VE point estimates (95% CI) based on the hazard ratio for subgroup analysis of efficacy of participants between age ≥ 18 and < 65 years without risk (at screening) for severe COVID-19, participants between age ≥ 18 and < 65 years with risk for severe COVID-19, and participants ≥ 65 years of age who had adjudicated severe COVID-19 starting 14 days after second injection were 97.9% (84.9%, 99.7%), 100%, and 96.9% (77.1%, 99.6%), respectively (Table 14.2.2.2.3.6.3).

Subgroup analysis of efficacy by race for participants who had adjudicated severe COVID-19 starting 14 days after second injection in the PP Set consistently showed more cases in the placebo groups than in the mRNA-1273 group for all racial subgroups experiencing cases, and VE point estimates were similar between races (Table 14.2.2.2.3.6.5). Analysis of some subgroups was limited by the low number of participant in each treatment group, but for those subgroups with over 250 combined participants (White, Black or African American, Asian, Multiple, Other, or Unknown), VE point estimates based on the hazard ratio ranged from 97.8% to 100%.

Similarly, subgroup analysis of efficacy in participants grouped by risk for severe COVID-19 at screening who had adjudicated severe COVID-19 starting 14 days after second injection in the PP Set showed more cases in the placebo group than in the mRNA-1273 group for all subgroups analyzed (Table 14.2.2.2.3.6.7). As anticipated, participants at risk had a higher overall frequency of severe COVID-19 (1.4% and < 0.1% in the placebo and mRNA-1273 groups, respectively) compared with participants not at risk (0.6% and <0.1%, respectively). The VE point estimates (95% CI) based on the hazard ratio for at risk and no risk subgroups were similar at 97.9% (84.6%, 99.7%) and 98.5% (88.9%, 99.8%). Consistent VE point estimates were observed in subgroup analyses of participants with 1 risk factor, at least 2 risk factors, chronic lung disease, significant cardiac disease, severe obesity, diabetes, liver disease, and HIV infection.

6.2.2 SARS-CoV-2 Infection Regardless of Symptomatology and Severity

The secondary efficacy endpoint, SARS-CoV-2 infection (definition in Section 4.2.2.2) regardless of COVID-19 symptomatology and severity, includes both symptomatic COVID-19 cases and asymptomatic SARS-CoV-2 infection cases in participants with baseline negative SARS-CoV-2 status (PP Set or mITT Set). The SARS-CoV-2 infection cases in participants with baseline negative SARS-CoV-2 status were detected by positive RT-PCR tests with or without eligible symptoms or by positive bAb specific to SARS-CoV-2 N protein as measured by Roche Elecsys at scheduled visits/timepoints.

At the PDV/unblinding visit, both RT-PCR test and bAb against NP (Roche Elecsys) were performed. Including these results from the scheduled PDV visits provides a complete view of VE of mRNA-1273 to prevent SARS-CoV-2 infection, including asymptomatic infection, throughout the observation period of Part A. For the efficacy endpoints of all SARS-CoV-2 infection and asymptomatic infection, analyses including PDV visits were performed (ie, RT-PCR and Elecsys results at PDV visits were taken into consideration if the PDV visits occurred at or before the data cutoff date of 26 Mar 2021).

Including the RT-PCR and Elecsys results from the PDV, there were a total of 1,619 SARS-CoV-2 infections starting 14 days after second injection in the PP Set (1,339 cases in the placebo group and 280 cases in the mRNA-1273 group); the VE point estimate (95% CI) based on the hazard ratio was 82.0% (79.5%, 84.2%) (Table 6-6). Sensitivity analysis of VE from randomization through the PDV in the mITT Set was performed (Table 14.2.2.3.5.2.2). There were a total of 1,857 SARS-CoV-2 infections (1,522 cases in the placebo group and 335 cases in the mRNA-1273 group); the VE point estimate (95% CI) based on the hazard ratio was 80.7% (78.2%, 82.8%). These results further confirm the high and persistent efficacy of mRNA-1273 in this study.

Table 6-6: Analysis of Vaccine Efficacy of mRNA-1273 to Prevent SARS-CoV-2 Infection Regardless of Symptomatology and Severity Starting 14 Days After the Second Injection Including Participant Decision Visit (Per-Protocol Set)

	Placebo (N=14164)	mRNA-1273 (N=14287)
Number of subjects with SARS-CoV-2 infection regardless of symptomatology and severity, n (%)	1339 (9.5)	280 (2.0)
Number of subjects censored, n (%)	12825 (90.5)	14007 (98.0)
Vaccine efficacy based on hazard ratio (95% CI) [a]		0.820 (0.795, 0.842)
Person-years [b]	5442.4	5755.2
Incidence rate per 1,000 person-years (95% CI) [c]	246.032 (233.029, 259.572)	48.652 (43.120, 54.697)
Vaccine efficacy based on incidence rate (95% CI) [d]		0.802 (0.775, 0.827)

Abbreviations: CI = confidence intervals.

[a] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor.

[b] Person-years is defined as the total years from randomization date to the date of SARS-CoV-2 infection, last date of study participation, or efficacy data cutoff date, whichever is earlier.

[c] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

[d] VE is defined as 1 – ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years.

Source: Table 14.2.2.3.1.1.2.

The summary of SARS-CoV-2 infection cases from randomization including the PDV by time period in the mITT Set is included in Table 6-7. The incidence of SARS-CoV-2 infection was higher in the placebo group over each time period starting in the period from randomization up to 14 days after the first injection, consistent with the corresponding primary analysis for adjudicated COVID-19 cases. The cumulative incidence rate curves for SARS-CoV-2 infection, regardless of COVID-19 symptomatology and severity starting after randomization and including the PDV in the mITT Set also shows a consistent picture (Figure 14.2.2.3.1.4.2), indicating early onset of protection. Thereafter, for the remainder of the observation period for Part A, the cumulative incidence rate for the placebo group increased steadily while it remained stable and low in the mRNA-1273 group.

Table 6-7: Summary of SARS-CoV-2 Infection Regardless of Symptomatology and Severity Starting After Randomization and Including Participant Decision Visit by Time Period (mITT Set)

	Placebo (N=14745)	mRNA-1273 (N=14746)
Number of subjects with SARS-CoV-2 infection regardless of symptomatology and severity, n (%)	1522 (10.3)	335 (2.3)
Number of events		
From randomization up to 14 days after first injection	11	6
>=14 up to 21 days after first injection	8	1
>=21 days after first injection up to second injection	59	8
From second injection up to 7 days after second injection	79	34
>=7 up to 14 days after second injection	13	0
>=14 up to 28 days after second injection	63	9
>=28 up to 56 days after second injection	221	29
>=56 up to 84 days after second injection	292	29
>=84 up to 112 days after second injection	318	61
>=112 days after second injection	458	158

Source: Table 14.2.1.1.2.3.4.2.

Analyses of VE of mRNA-1273 to prevent SARS-CoV-2 infection regardless of COVID-19 symptomatology and severity up to but not including PDV visits were also performed for infection cases starting 14 days after second injection in the PP Set. Sensitivity analyses with various starting points of counting cases based on the PP Set and mITT Set were performed and the results were included in Section 14.2.3. Subgroup analyses were also performed and the results in each subgroup examined were consistently high.

6.2.3 COVID-19 Starting 14 Days After the First Injection

The VE of mRNA-1273 to prevent adjudicated cases of COVID-19 starting 14 days after first injection were similar to the VE for the primary endpoint (Section 6.1.2.1). A total of 825 participants had a SARS-CoV-2 infection starting 14 days after first injection in the PP Set

(769 cases in the placebo group and 56 cases in the mRNA-1273 group); the VE point estimate (95% CI) based on the hazard ratio was 93.3% (91.1%, 94.9%; Table 14.2.1.1.1.1.1.2). Interpretation of this result is limited because more than 96% of participants received their second dose and the analysis included cases that occurred after the second dose.

Additional analyses were performed based on eligible symptoms for COVID-19 and positive RT-PCR (without adjudication); the results were similar to those from adjudicated cases and are presented in Section 14.2.3.

Similar results were noted for the sensitivity analysis based on the mITT Set (VE point estimate [95% CI] based on the hazard ratio was 92.9% [90.8%, 94.5%]; Table 14.2.2.1.3.3.2).

An exploratory analysis of VE of mRNA-1273 to prevent adjudicated COVID-19 starting 14 days after the first injection was carried out for participants in the mITT Set who received only 1 injection, and the results are provided in Table 14.2.2.1.3.3.3.

6.2.4 Secondary Definition of COVID-19

The VE of mRNA-1273 to prevent COVID-19 starting 14 days after second injection using the secondary definition for COVID-19 (only 1 symptom required from a broader list of symptoms published by the CDC; Section 2) was consistent with the VE for the primary endpoint. A total of 865 participants had a SARS-CoV-2 infection starting 14 days after second injection in the PP Set (807 cases in the placebo group and 58 cases in the mRNA-1273 group); the VE point estimate (95% CI) based on the hazard ratio was 93.2% (91.4%, 94.9%; Table 6-8).

Table 6-8: Analysis of Vaccine Efficacy of mRNA-1273 to Prevent Secondary Definition of COVID-19* Starting 14 Days After the Second Injection (Per-Protocol Set)

	Placebo (N=14164)	mRNA-1273 (N=14287)
Number of subjects with secondary definition of COVID-19*, n (%)	807 (5.7)	58 (0.4)
Number of subjects censored, n (%)	13357 (94.3)	14229 (99.6)
Vaccine efficacy based on hazard ratio (95% CI) [a]		0.934 (0.914, 0.949)
Person-years [b]	5433.4	5728.7
Incidence rate per 1,000 person-years (95% CI) [c]	148.525 (138.453, 159.136)	10.124 (7.688, 13.088)
Vaccine efficacy based on incidence rate (95% CI) [d]		0.932 (0.911, 0.949)

Abbreviations: CI = confidence intervals; RT-PCR = reverse transcription polymerase chain reaction.

* With the censoring rules for efficacy analyses. COVID-19 case is based on eligible symptoms and positive RT-PCR within 14 days. If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys.

[a] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor.

[b] Person-years is defined as the total years from randomization date to the date of secondary definition of COVID-19, the date of earliest positive RT-PCR or Elecsys at scheduled visits, last date of study participation, or efficacy data cutoff date, whichever is earlier.

[c] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

[d] VE is defined as 1 – ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years.

Source: Table 14.2.2.4.2.1.1

Similar results were noted for the sensitivity analysis based on the mITT Set (VE point estimate [95% CI] based on the hazard ratio was 93.1% [91.0%, 94.7%]) (Table 14.2.2.4.2.1.2).

Sensitivity analyses of COVID-19 prevention starting after randomization, based on the mITT Set and using the secondary definition of COVID-19, showed a VE point estimate based on the hazard ratio (95% CI) of 92.1% ([90.0%, 93.8%]) (Table 14.2.2.4.2.5.2).

In the mITT Set, the number of cases of COVID-19 by the secondary definition starts to diverge between placebo and mRNA-1273 groups in the time period from randomization up to 14 days after the first injection (Table 14.2.1.1.2.4.2.4), consistent with the corresponding analysis for COVID-19 cases (Table 6-3). The cumulative incidence rate curves for COVID-19 based on the

secondary definition for COVID-19 and starting after randomization in the mITT Set (Figure 14.2.2.4.2.1.4) present a picture consistent with the corresponding curves for COVID-19 based on the primary definition of COVID-19 (Figure 6-1), indicating early onset of protection.

6.2.5 Death Caused by COVID-19

Analysis of mRNA-1273 to prevent COVID-19-related death starting 14 days after the second injection showed that 3 participants died, all in the placebo group during the placebo-controlled, randomized Part A of the study. For this final analysis of efficacy for Part A, based on the PP Set, the VE point estimate (95% CI) was 100% (not estimable, 100%) (Table 14.2.1.1.1.1.1.2).

There was one death caused by COVID-19 in the mRNA-1273 group, participant US3702010. After randomization, the participant only received one dose and thus was not included in the estimates of VE of mRNA-1273 against death caused by COVID-19 14 days after the second injection. This subject is included in the listing of deaths (Listing 16.2.12) and the listing of unsolicited AEs in participants who died (Listing 16.2.7.27).

6.2.6 Asymptomatic SARS-CoV-2 Infection

Prevention of asymptomatic SARS-CoV-2 infection was analyzed using the PP Set and mITT Set and was identified by seroconversion against N protein (by the Elecsys assay) or detection by RT-PCR in the absence of symptoms. As disease cases (COVID-19 or secondary definition of COVID-19) were competing events for asymptomatic SARS-CoV-2 infections, a competing risk method (FG subdistribution hazard model) was used to estimate the VE of mRNA-1273 to prevent asymptomatic SARS-CoV-2 infection (Section 4.2.2.2). Details on the determination of asymptomatic SARS-CoV-2 infection are provided in mRNA-1273-P301 SAP Section 6.3.2.1.4 (Appendix 16.1.9). The sensitivity of the detection of asymptomatic infection was limited by the following: the frequency of assessment of seroconversion to anti nucleoprotein; the kinetics of seroconversion, which may take one to two weeks after the initial infection; and the fixed timepoints at which serum was sampled and analyzed.

At the PDV/unblinding visit, both nasal swab samples for RT-PCR test and serum samples for bAb against N protein (Roche Elecsys) were taken. Including these results at the scheduled PDV visits provides a complete view of VE of mRNA-1273 to prevent asymptomatic SARS-CoV-2 infection throughout the observation period of Part A.

Including the RT-PCR and Elecsys results at the PDV, there were a total of 712 asymptomatic SARS-CoV-2 infection cases starting 14 days after the second injection in the PP Set (498 cases in the placebo group and 214 cases in the mRNA-1273 group); the VE point estimate (95% CI) based on the hazard ratio was 63.0% (56.6%, 68.5%) (Table 6-9). Sensitivity analysis of VE to prevent asymptomatic infection from randomization and including the PDV in the mITT Set was

performed (Table 14.2.2.6.2.5.2.2). There were a total of 836 asymptomatic SARS-CoV-2 infection cases (583 cases in the placebo group and 253 cases in the mRNA-1273 group); the VE point estimate (95% CI) was 61.6% (55.5%, 66.9%) using the competing risk method. This analysis provides a complete view of VE of mRNA-1273 against asymptomatic infection and further confirms that vaccination with mRNA-1273 protects against asymptomatic infection (albeit at a lower VE than for symptomatic cases).

The cumulative incidence rate curves for asymptomatic SARS-CoV-2 infection starting after randomization in the mITT Set (Figure 14.2.2.6.2.1.6.2) are similar to the corresponding curves for COVID-19 based on the primary definition of COVID-19 starting after randomization in the mITT Set (Figure 6-1).

Table 6-9: Analysis of Vaccine Efficacy of mRNA-1273 to Prevent Asymptomatic SARS-CoV-2 Infection Starting 14 Days After the Second Injection Including the Participant Decision Visit Using the Competing Risk Method (Per-Protocol Set)

	Placebo (N=14164)	mRNA-1273 (N=14287)
Number of subjects with asymptomatic SARS-CoV-2 infection, n (%)	498 (3.5)	214 (1.5)
Number of subjects with competing event, n (%)	863 (6.1)	62 (0.4)
Number of subjects censored, n (%)	12803 (90.4)	14011 (98.1)
Vaccine efficacy based on hazard ratio (95% CI) [a]		0.630 (0.566, 0.685)
Person-years [b]	5442.1	5756.1
Incidence rate per 1,000 person-years (95% CI) [c]	91.508 (83.646, 99.909)	37.178 (32.363, 42.507)

Abbreviations: CI = confidence intervals; RT-PCR = reverse transcription polymerase chain reaction

RT-PCR test and Elecsys anti-SARS-CoV-2 assay results at post-baseline scheduled visits are considered in case definition. Disease cases (COVID-19 or second definition of COVID-19) are considered as competing events for asymptomatic SARS-CoV-2 infection.

[a] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using Fine and Gray's sub-distribution hazard model with disease cases as competing events and with the treatment group as a covariate, adjusting for stratification factor.

[b] Person-years is defined as the total years from randomization date to the earliest of the date of symptomatic SARS-CoV-2 infection, the date of asymptomatic SARS-CoV-2 infection, last date of study participation, or efficacy data cutoff date, whichever is earlier.

[c] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

Source: Table 14.2.2.6.2.1.1.2.

Analyses of VE of mRNA-1273 to prevent asymptomatic SARS-CoV-2 infection up to but not including PDV visits were also performed with infection cases starting 14 days after second injection in the PP Set. Sensitivity analyses with various starting points of counting cases based on the PP Set and mITT Set were performed and the results are included in Section 14.2.3.

6.2.7 COVID-19 Regardless of Prior SARS-CoV-2 Infection

The VE results of mRNA-1273 in participants with adjudicated COVID-19 regardless of prior SARS-CoV-2 infection starting 14 days after the second injection were similar to the VE for the primary endpoint. A total of 812 participants had a SARS-CoV-2 infection starting 14 days after second injection in the FAS (754 cases in the placebo group and 58 cases in the mRNA-1273

group); the VE point estimate (95% CI) based on the hazard ratio was 92.8% (90.6%, 94.5%; Table 6-10). This analysis cannot be interpreted as to the relative contribution of vaccination to the protection already afforded by prior exposure because the number of previously infected participants at baseline was too small to have an impact on the combined analysis (Table 14.1.3.2.1).

Additional analyses were performed based on eligible symptoms for severe COVID-19 and positive RT-PCR (cases not adjudicated); these results are presented in Section 14.2.3.

Table 6-10: Analysis of Vaccine Efficacy of mRNA-1273 to Prevent COVID-19* Based on Adjudication Committee Assessments Starting 14 Days After the Second Injection Regardless of Prior SARS-CoV-2 Infection (Full Analysis Set)

	Placebo (N=15166)	mRNA-1273 (N=15180)
Number of subjects with COVID-19*, n (%)	754 (5.0)	58 (0.4)
Number of subjects censored, n (%)	14412 (95.0)	15122 (99.6)
Vaccine efficacy based on hazard ratio (95% CI) [a]		0.928 (0.906, 0.945)
Person-years [b]	5768.0	6027.8
Incidence rate per 1,000 person-years (95% CI) [c]	130.721 (121.556, 140.394)	9.622 (7.306, 12.439)
Vaccine efficacy based on incidence rate (95% CI) [d]		0.926 (0.904, 0.945)

Abbreviations: CI = confidence intervals; RT-PCR = reverse transcription polymerase chain reaction.

* With the censoring rules for efficacy analyses. COVID-19 case is based on eligible symptoms and positive RT-PCR within 14 days. If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys.

[a] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor.

[b] Person-years is defined as the total years from randomization date to the date of COVID-19, the date of earliest positive RT-PCR or Elecsys at scheduled visits, last date of study participation, or efficacy data cutoff date, whichever is earlier.

[c] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.

[d] VE is defined as 1 – ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years.

Source: Table 14.2.2.7.3.1.

Sensitivity to different starting days for counting participants with adjudicated COVID-19 regardless of prior SARS-CoV-2 infection starting after randomization was evaluated; these results are presented in Section 14.2.3.

6.3 Efficacy Results for Exploratory Endpoints

6.3.1 Vaccine Efficacy to Reduce Duration and Presence/Severity of COVID-19 Symptoms

Participants who experienced COVID-19 symptoms and subsequently tested positive for COVID-19 during an Illness Visit were monitored daily for the duration and severity of symptoms (Section 3.7.2.2). Symptom scores aggregated over the convalescence period for adjudicated COVID-19 cases showed a higher mean total COVID-19 symptom score in the placebo group (60.6) than in the mRNA-1273 group (26.8; Table 6-11).

The VE point estimate (95% CI) of mRNA-1273 for mean of total COVID-19 symptoms score in the PP Set was 38.2% (16.5%, 54.3%), based on 1 – the ratio of the means of total COVID-19 symptoms score. This indicates meaningful protection by mRNA-1273 against symptoms over the convalescent period in participants who were adjudicated COVID-19 cases.

Table 6-11: Vaccine Efficacy of mRNA-1273 on Duration and Severity of COVID-19 Symptoms (Per-Protocol Set – Subjects with COVID-19 Based on Adjudication Committee Assessments)

	Placebo (N=770)	mRNA-1273 (N=57)
Mean of total COVID-19 symptoms score	60.6	26.8
Treatment comparison (mRNA-1273 vs. Placebo) [a]		
Ratio of the mean score		0.618
95% CI		0.457, 0.835
1 - ratio of the mean score		0.382
95% CI		0.165, 0.543

Abbreviations: CI = confidence interval.

Symptom Score: 0 = None, 1 = Mild, 2 = Moderate, 3 = Severe.

Convalescence period: up to (<=28 days) after COVID-19 onset date.

Total symptom scores are calculated as the sum of recorded daily symptoms scores of all symptoms during the convalescence period.

Quartiles (across the two treatment groups) based on total symptom scores are used in proportional means model.

[a] Vaccine Efficacy is estimated using proportional means model including vaccination group as fixed effect and stratified with stratification factor at randomization.

Source: Table 14.2.3.3.2.

Symptom scores collected over the convalescence period for adjudicated COVID-19 cases were summarized by randomization stratum (overall, age ≥ 18 to < 65 years and not at risk, age ≥ 18

to < 65 years and at risk, and age ≥ 65 years) for number of subjects and scores per quartile, mean daily score, number of days with pre-specified symptom scores, highest temperature, and lowest oxygen saturation (Table 14.2.3.3.1). The number of placebo participants within each score quartile (based on the distribution of scores across both treatment groups) was similar, while there were relatively fewer mRNA-1273 participants in the higher quartiles (ie, above the median) than in the lower quartiles. Mean daily symptom scores, the number of days with at least 1 COVID-19 symptom score > 0, ≥ 2, or > 3, and the number of days with at least 2 COVID-19 symptom scores ≥ 2 were lower among participants receiving mRNA-1273 than among those receiving placebo. Highest temperature and lowest oxygen saturation data were similar between the 2 groups. These trends were consistent among participants age ≥ 18 to < 65 years and not at risk, age ≥ 18 to < 65 years and at risk, and age ≥ 65 years. However, the small number of participants in the mRNA-1273 groups for the latter 2 stratified groups was small (n = 12 and 7, respectively), thereby limiting the interpretation of these results.

6.3.2 Vaccine Efficacy Against Burden of Disease

The mean BOD score for the mRNA-1273 group was 0.0 versus 0.1 for the placebo group (Table 14.2.3.1.1.3). The VE point estimate (95% CI) of mRNA-1273 for BOD in the PP Set was 93.2% (91.0%, 94.8%), based on 1 – the ratio of the mean BOD scores. Although this is a statistically significant difference over the entire PP Set, the result is driven by high vaccine efficacy and the numerically dominant prevalence of mild to moderate disease.

6.3.3 Vaccine Efficacy Against Burden of Infection

The mean BOI score for the mRNA-1273 group was 0.01 versus 0.06 for the placebo group (Table 14.2.3.2.1.3). The VE point estimate (95% CI) of mRNA-1273 for BOI in the PP Set was 91.2% (89.0%, 93.0%), based on 1 – the ratio of the mean BOI score. Although this is a statistically significant difference over the entire PP Set, the result is driven by high vaccine efficacy and the numerically dominant prevalence of mild to moderate disease that was detected (especially versus asymptomatic infection).

6.3.4 Efficacy Against Viral Load

Viral load during infection was assessed in adjudicated COVID-19 cases (baseline negative, negative RT-PCR and Elecsys at Day 29, and negative Elecsys at Day 57) in the PP Set during Part A, from the Illness Visit (Day 1 of the convalescent period) through Day 28 of the convalescent period (refer to Genotyping Report [Appendix 16.5]). From Day 1 through Day 9 of the convalescent period, the mean number of viral copies detected in the placebo arm was significantly higher than those in the mRNA-1273 arm (Figure 3 of the Genotyping Report

[Appendix 16.5]), with the number being 100-fold lower among mRNA-1273 cases at Day 1 and 10-fold lower at Day 9.

6.3.5 All-Cause Mortality After Randomization

All-cause mortality after randomization was assessed in the PP Set (Table 14.2.2.8.1.1). A total of 24 participants died, 12 in each of the placebo and mRNA-1273 treatment groups.

6.4 Genotypic Analysis of Variants

The Genotyping Report is provided in Appendix 16.5.

Sequence information was obtained from all available SARS-CoV-2 PCR positive NP samples collected from July 2020 through May 2021 from participants in Part A. Sequences of the gene encoding the spike protein gene were generated from 832 different samples, corresponding to 791 trial participants (720 from placebo recipients, 71 from mRNA-1273 recipients). To assess the relative prevalence of key variant lineages detected in the clinical dataset, Pango lineages were inferred for each isolate based on amino acid mutations detected in the spike protein gene. The prevalences of selected lineages were then compared to those from a United States time-matched subset of the Global Initiative on Sharing All Influenza Data (GISAID) database. This comparison revealed that the sequences detected in adjudicated case samples were essentially a representation of the circulating strains in the US during the trial, with similar frequencies between the Part A and GISAID sample populations and D614G the predominant variant. Summaries of the number of variants by lineage in adjudicated cases starting after randomization are presented for the PP Set and mITT Set in Ad Hoc Table 14.2.1.1.2.1.4.1 and Ad Hoc Table 14.2.1.1.2.1.4.2, respectively.

6.4.1 Efficacy Against Variants

Consistent with current CDC classifications of variants and the lineages observed during Part A, exploratory analyses of VE of mRNA-1273 were conducted for variants of concern (VOC), variants of interest (VOI), and the California variants B.1.427 and B.1.429. Vaccine efficacy and 95% CIs were estimated using FG's sub-distribution hazard model with disease cases as competing events and with the treatment group as a covariate, adjusting for stratification factor. Overall, the VEs estimated in the study were driven by VE against the predominant D614G strain.

A VOC is a variant for which there is evidence of an increase in transmissibility, more severe disease (increased hospitalizations or deaths), significant reduction in neutralization by antibodies generated during previous infection or vaccination, reduced effectiveness of treatments or vaccines, or diagnostic detection failures. For VOC, the VE point estimate

(95% CI) based on the hazard ratio for 16 participants in the placebo group and 3 participants in the mRNA-1273 group was 82.4% (40.4%, 94.8%; Ad Hoc Table 14.2.2.6.2.1.3).

A VOI is a variant with specific genetic markers that have been associated with changes to receptor binding, reduced neutralization by antibodies generated against previous infection or vaccination, reduced efficacy of treatments, potential diagnostic impact, or predicted increase in transmissibility or disease severity. For VOI, the VE point estimate based on the hazard ratio for 2 participants in the placebo group and none in the mRNA-1273 group was 100% (Ad Hoc Table 14.2.2.6.2.1.4).

An exploratory analysis of VE of mRNA-1273 was performed for California variant data combined (B.1.427 and B.1.429) using the competing risk method. The FG sub-distribution hazard model was used, and COVID-19 cases associated with variants other than the California variants were considered as competing risks. For the California variants, the VE point estimate (95% CI) based on the hazard ratio for 15 participants in the placebo group and 3 participants in the mRNA-1273 group was 81.2% (36.1%, 94.5%; Ad Hoc Table 14.2.2.6.2.1.1).

These exploratory analyses have the following limitations:

- The 100-fold lower viral shedding in the mRNA-1273 COVID-19 breakthrough cases hindered efforts to generate an unbiased sequence data set. The success rate in obtaining good quality sequences from mRNA-1273 breakthrough cases was 50% or less, while it was over 80% for cases in the placebo group.
- The sample size of variants detected was small, making it difficult to accurately assess the true proportions of viral variants and associated VEs.

6.5 Immunogenicity

A total of 1591 participants were selected for the Random Subcohort for Immunogenicity (335 participants in the placebo group; 1256 participants in the mRNA-1273 group) (Table 14.1.2.5; refer to Section 4.1.3 for definitions of the analysis sets). Of these, 1457 participants (91.6%) were included in the PP Random Subcohort for Immunogenicity (272/335 participants [81.2%] in the placebo group; 1185/1256 participants [94.3%] in the mRNA-1273 group) (Table 14.1.2.5).

A total of 134 participants (63 participants [18.8%] in the placebo group; 71 participants [5.7%] in the mRNA-1273 group) were excluded from the PP Random Subcohort for Immunogenicity Set (Table 14.1.2.5). The most common reason for exclusion was participant did not receive dose 2 per schedule (52 participants in the placebo group; 44 participants in the mRNA-1273 group), followed by HIV infection (4 participants in the placebo group; 21 participants in the mRNA-1273 group). A total of 8 participants were excluded for receiving dose 2 outside of the

window period for the PP Set (3 participants in the placebo group; 5 participants in the mRNA-1273 group); 4 participants had other major protocol deviations (3 participants in the placebo group; 1 participant in the mRNA-1273 group), and 1 participant in the placebo group was excluded for receiving the incorrect vaccination.

6.5.1 SARS-CoV-2 Spike Protein-Specific Antibodies as Measured by Binding Antibody and Pseudovirus Neutralizing Antibody Assays

The results for the immunogenicity endpoints are presented through Day 57 (Month 2).

6.5.1.1 SARS-CoV-2 Spike Protein-Specific Binding Antibodies as Measured by MesoScale Discovery Assay

As expected, the baseline GM level of SARS-CoV-2 S-protein IgG antibodies, as measured by MSD Multiplex assay, was higher at baseline in participants positive for SARS-CoV-2 (approximately 7000 AU/mL in both treatment groups) than those who were negative for SARS-CoV-2 at baseline (approximately 115 AU/mL in both treatment groups) (Table 6-12).

mRNA-1273 is highly immunogenic in both SARS-CoV-2 baseline-positive and baseline-negative participants, as indicated by increased GM levels of anti-SARS-CoV-2 S-protein IgG antibodies on Day 29 (28 days after the first injection), which were further increased on Day 57 (28 days after the second injection) (Table 6-12 and Figure 6-3).

In SARS-CoV-2 baseline-negative mRNA-1273 treated participants, the GM level (95% CI) on Day 29 was 35752.817 AU/mL (33375.81, 38299.12) (GM fold-rise [GMFR] approximately 310), with 99.1% of participants having seroresponse. Seroresponse at a subject level was defined as a change from below the LLOQ to equal or above the LLOQ, or at least a 1.9-fold rise (critical fold rise statistically derived based on the variabilities of the MSD IgG S-protein assay at different sample dilutions; refer to Section 4.2.4.1) if baseline was equal to or above the LLOQ. On Day 57, the GM level (95% CI) increased to 316448.298 AU/mL (300071.44, 333718.95) (GMFR approximately 2737), with 99.6% of participants showing seroresponse (Table 6-12).

In SARS-CoV-2 baseline-positive mRNA-1273 treated participants, the GM levels on Day 29 were higher than those observed in baseline-negative mRNA-1273 treated participants and were similar to those observed on Day 57 in baseline-negative mRNA-1273 treated participants, indicating that the first injection of mRNA-1273 acts like a booster in participants with previous SARS-CoV-2 infection. The GM level (95% CI) was 410049.212 AU/mL (313904.05, 535642.52) on Day 29 (GMFR approximately 60) and increased to 668685.136 AU/mL

(570883.47, 783241.82) on Day 57 (GMFR approximately 96), with 97.6% of participants showing seroresponse on Day 29 and Day 57 (Table 6-12).

In the placebo group, the GM levels remained unchanged over time for baseline-negative participants (Day 57 GMFR [95% CI] of 1.10 [0.94, 1.28]) and baseline-positive participants (Day 57 0.73 [0.64, 0.83]) with only slight fluctuations (Table 6-12 and Figure 6-3).

Similar baseline results were observed for both subgroups stratified by age (≥ 18 to < 65 years and ≥ 65 years) in both SARS-CoV-2 baseline-negative and baseline-positive participants (Table 6-13 and Figure 6-4). In baseline-negative mRNA-1273 treated participants, the GM levels on Day 29 and Day 57 were lower in participants ≥ 65 years than those observed in participants ≥ 18 to < 65 years; however, seroresponse rates remained high (98.9% to 100%) across both age groups on Day 29 and Day 57. In baseline-positive mRNA-1273 treated participants, the GM levels on Day 29 were lower in participants ≥ 65 years than those observed in participants ≥ 18 to < 65 years, while Day 57 levels were similar between age groups; seroresponse rates ranged from 95.7% to 100% across both age groups on Day 29 and Day 57.

Mixed-model repeated measures and ANCOVA analyses showed consistent results (Table 14.2.4.1.1.2.3.1 and Table 14.2.4.1.1.3.3.1, respectively). These results can be found in Section 14. In addition, reverse cumulative distribution plots can be found in Section 14.

Table 6-12: Summary of Binding Antibody Specific to SARS-CoV-2 Spike Protein by MesoScale Discovery Assay by Baseline SARS-CoV-2 Status (Per-Protocol Random Subcohort for Immunogenicity)

Timepoint Data Category Statistic	Placebo (N=142)	mRNA-1273 (N=1055)

Abbreviations: CI = confidence intervals; Min = minimum; Max = maximum; GM = geometric mean; MSD = MesoScale Discovery.

N1 = Number of subjects with non-missing data at baseline and the corresponding timepoint.

Antibody values reported as below the lower limit of quantification (LLOQ) are replaced by 0.5 x LLOQ. Values greater than the upper limit of quantification (ULOQ) are replaced by the ULOQ if actual values are not available.

[a] Number of subjects with non-missing data at the corresponding timepoint.

[b] 95% CI is calculated based on the t-distribution of the log-transformed values or the difference in the log-transformed values for GM value and GM fold-rise, respectively, then back transformed to the original scale for presentation.

[c] Seroresponse at a subject level is defined as a change from below the LLOQ to equal or above the LLOQ, or at least a 1.9-fold rise if baseline is equal to or above the LLOQ.

[d] Number of subjects meeting the criterion at the time point. Percentages are based on N1.

[e] 95% CI is calculated using the Clopper-Pearson method.

[f] >= z-fold increase from baseline at participant level is defined as a >= z x LLOQ for participants with baseline antibody level below the LLOQ, or a z-times or higher level ratio in participants with baseline antibody level equal to or above the LLOQ.

6.5.1.2 SARS-CoV-2 Spike Protein-Specific Binding Antibodies as Measured by ELISA

Overall, the results for SARS-CoV-2- S-2P protein IgG (VSDVAC65), as measured by ELISA assay were similar to those measured by MSD Multiplex assay (Section 6.5.1.1).

As anticipated, the baseline GM level was higher in SARS-CoV-2 baseline-positive participants (approximately 24 AU/mL in both treatment groups) than in SARS-CoV-2 baseline-negative participants (approximately 0.7 AU/mL in both treatment groups) (Table 6-14).

mRNA-1273 is highly immunogenic in both SARS-CoV-2 baseline-positive and baseline-negative participants, as indicated by increased GM levels of S-2P protein IgG on Day 29, which were further increased on Day 57 (Table 6-14 and Figure 6-5).

In SARS-CoV-2 baseline-negative mRNA-1273 treated participants, the S-2P protein IgG GM level (95% CI) on Day 29 was 106.97 AU/mL (100.64, 113.69) (GMFR approximately 149), with 99.0% of participants showing seroresponse. Seroresponse at a subject level was defined as a change from below the LLOQ to equal or above the LLOQ, or at least a 4.6-fold rise (critical fold rise based on the similarity of variabilities of the ELISA IgG S-2P assay; refer to Section 4.2.4.1) if baseline was equal to or above the LLOQ. On Day 57, the GM level (95% CI) increased to 694.75 AU/mL (664.75, 726.10) (GMFR approximately 971), with 99.6% of participants showing seroresponse.

In SARS-CoV-2 baseline-positive mRNA-1273 treated participants, the S-2P protein IgG GM levels on Day 29 were higher than those observed in baseline-negative mRNA-1273 treated participants, and were similar to those observed on Day 57 in baseline-negative mRNA-1273 treated participants. The GM level (95% CI) was 772.15 AU/mL (628.74, 948.27) on Day 29 (GMFR approximately 32) and increased to 1097.47 AU/mL (950.57, 1267.08) on Day 57 (GMFR approximately 46), with 96.2% and 95.4% of participants showing seroresponse on Day 29 and Day 57, respectively (Table 6-14 and Figure 6-5).

In the placebo group, the S-2P protein IgG GM levels remained unchanged over time for baseline-negative participants (Day 57 GMFR [95% CI] of 1.06 [0.92, 1.23]) and baseline-positive participants (0.69 [0.62, 0.76]) with only slight fluctuations (Table 6-14 and Figure 6-5).

Similar S-2P protein IgG levels were observed for both subgroups stratified by age (≥ 18 to < 65 years and ≥ 65 years) in both SARS-CoV-2 baseline-negative and baseline-positive participants (Table 6-15 and Figure 6-6). In baseline-negative participants, the GM levels on Day 29 and Day 57 were lower in participants ≥ 65 years than those observed in participants

≥ 18 to < 65 years; however, seroresponse rates remained high (98.9% to 100%) across both age groups on Day 29 and Day 57.

In baseline-positive mRNA-1273 treated participants, the GM levels on Day 29 and Day 57 were similar between participants ≥ 65 years and ≥ 18 to < 65 years (with overlapping 95% CIs); seroresponse rates ranged from 91.3% to 97.2% across both age groups on Day 29 and Day 57.

Abbreviations: CI = confidence intervals; Min = minimum; Max = maximum; ELISA = enzyme-linked immunosorbent assay; GM = geometric mean. N1 = Number of subjects with non-missing data at baseline and the corresponding timepoint.

Antibody values reported as below the lower limit of quantification (LLOQ) are replaced by 0.5 x LLOQ. Values greater than the upper limit of quantification (ULOQ) are replaced by the ULOQ if actual values are not available.

[a] Number of subjects with non-missing data at the corresponding timepoint.

[b] 95% CI is calculated based on the t-distribution of the log-transformed values or the difference in the log-transformed values for GM value and GM fold-rise, respectively, then back transformed to the original scale for presentation.

[c] Seroresponse at a subject level is defined as a change from below the LLOQ to equal or above the LLOQ, or at least a 4.6-fold rise if baseline is equal to or above the LLOQ.

[d] Number of subjects meeting the criterion at the time point. Percentages are based on N1.

[e] 95% CI is calculated using the Clopper-Pearson method.

[f] >= z-fold increase from baseline at participant level is defined as a >= z x LLOQ for participants with baseline antibody level below the LLOQ, or a z-times or higher level ratio in participants with baseline antibody level equal to or above the LLOQ.

6.5.1.3 SARS-CoV-2 Spike Protein-Specific Neutralizing Antibodies as Measured by Pseudotyped Virus Neutralization Assay

As expected, the baseline GM titers for ID_{50} neutralizing antibodies against SARS-CoV-2 S-protein, as measured by PsVNA, were higher at baseline in participants who were positive for SARS-CoV-2 (approximately 83 for placebo group and 68 for mRNA-1273 treatment group) than in those who were negative for SARS-CoV-2 (approximately 9 and 10 for placebo and mRNA-1273 treatment groups, respectively; Table 6-16).

mRNA-1273 is highly immunogenic in both SARS-CoV-2 baseline-positive and baseline-negative participants, as indicated by increased ID_{50} GM titers on Day 29, which were further increased on Day 57 (Table 6-16 and Figure 6-7).

In SARS-CoV-2 baseline-negative mRNA-1273 treated participants, the GM ID_{50} titer (95% CI) on Day 29 was 54.866 (50.98, 59.04) (GMFR approximately 5.7), with 81.4% of participants showing seroresponse. Seroresponse to PsVNA ID_{50} titer at a subject level was defined as a change from below the LLOQ to equal or above the LLOQ, or at least 3.3 fold-rise (critical fold rise based on the similarity of variabilities of the PsVNA ID_{50}; refer to Section 4.2.4.1) if baseline was equal to or above LLOQ. On Day 57, the GM ID_{50} titer (95% CI) increased to 1081.124 (1019.80, 1146.14) (GMFR approximately 112.3), with 98.9% of participants showing seroresponse.

In SARS-CoV-2 baseline-positive mRNA-1273 treated participants, the ID_{50} GM titer levels on Day 29 were higher than those observed in baseline-negative participants, with titer levels that were similar to those observed on Day 57 in baseline-negative participants, supporting the observation that the first injection of mRNA1273 acts like a booster in participants with previous SARS-CoV-2 infection. The GM ID_{50} titer (95% CI) was 1478.910 (1069.60, 2044.86) on Day 29 (GMFR approximately 21.7) and increased to 3145.904 (2539.80, 3896.66) on Day 57 (GMFR approximately 46.2), with 87.7% and 94.6% of participants showing seroresponse on Day 29 on Day 57, respectively.

In the placebo group, the ID_{50} GM titers remained unchanged over time for SARS-CoV-2 baseline-negative participants (Day 57 GMFR [95% CI] of 1.07 [0.97, 1.18]) and SARS-CoV-2 baseline-positive participants on Day 57 (0.59 [0.50, 0.69]) with only slight fluctuations (Table 6-16 and Figure 6-7).

Similar results were observed for the ID_{80} titers; results and are summarized by baseline SARS-CoV-2 status in Table 6-16.

Similar baseline results were observed for both subgroups stratified by age (≥ 18 to < 65 years and ≥ 65 years) in both SARS-CoV-2 baseline-negative and baseline-positive participants

(Table 6-17 and Figure 6-8). In baseline-negative mRNA-1273 treated participants, the ID_{50} GM titers on Day 29 and Day 57 were lower in participants ≥ 65 years than those observed in participants ≥ 18 to < 65 years. The seroresponse rate was also lower in the older age group than in the younger age group on Day 29 (71.1% vs. 86.6%), with similar seroresponse rates observed in both age groups on Day 57 (99.4% vs. 98.6%). Nominal differences were observed between age groups in SARS-CoV-2 baseline-positive participants. Pseudovirus nAb ID_{80} titers are summarized by baseline SARS-CoV-2 status and age in Table 6-17.

Box plots of PsVNA ID_{80} titers by baseline SARS-CoV-2 status and age group for mRNA-1273 treated participants and placebo can be found in Section 14 (Figure 14.2.4.2.4.3.1 and Figure 14.2.4.2.4.4.1).

n (%) [d]	1 (0.8)	124 (95.4)
95% CI [e]	(0.0, 4.2)	(90.2, 98.3)

Abbreviations: CI = confidence intervals; Min = minimum; Max = maximum; GM = geometric mean.

N1 = Number of subjects with non-missing data at baseline and the corresponding timepoint.

Antibody values reported as below the lower limit of quantification (LLOQ) are replaced by 0.5 x LLOQ. Values greater than the upper limit of quantification (ULOQ) are replaced by the ULOQ if actual values are not available.

[a] Number of subjects with non-missing data at the corresponding timepoint.

[b] 95% CI is calculated based on the t-distribution of the log-transformed values or the difference in the log-transformed values for GMT and GMFR, respectively, then back transformed to the original scale for presentation.

[c] Seroresponse to pseudovirus neutralizing antibody ID_{50} titer at a subject level is defined as a change from below the LLOQ to equal or above the LLOQ, or at least a 3.3-fold rise if baseline is equal to or above the LLOQ. Seroresponse to pseudovirus neutralizing antibody ID_{80} titer at a subject level is defined as a change from below the LLOQ to equal or above the LLOQ, or at least a 2.3-fold rise if baseline is equal to or above the LLOQ.

[d] Number of subjects meeting the criterion at the time point. Percentages are based on N1.

[e] 95% CI is calculated using the Clopper-Pearson method.

[f] >= z-fold increase from baseline at participant level is defined as a >= z x LLOQ for participants with baseline antibody titer below LLOQ, or a z-times or higher titer ratio in participants with baseline antibody titer equal to or above the LLOQ.

Abbreviations: CI = confidence intervals; Min = minimum; Max = maximum.

N1 = Number of subjects with non-missing data at baseline and the corresponding timepoint.

Antibody values reported as below the lower limit of quantification (LLOQ) are replaced by 0.5 x LLOQ. Values greater than the upper limit of quantification (ULOQ) are replaced by the ULOQ if actual values are not available.

[a] Number of subjects with non-missing data at the corresponding timepoint.

[b] 95% CI is calculated based on the t-distribution of the log-transformed values or the difference in the log-transformed values for GMT and GMFR, respectively, then back transformed to the original scale for presentation.

[c] Seroresponse to pseudovirus neutralizing antibody ID_{50} titer at a subject level is defined as a change from below the LLOQ to equal or above the LLOQ, or at least a 3.3-fold rise if baseline is equal to or above the LLOQ. Seroresponse to pseudovirus neutralizing antibody ID_{80} titer at a subject level is defined as a change from below the LLOQ to equal or above the LLOQ, or at least a 2.3-fold rise if baseline is equal to or above the LLOQ.

	>=18 and <65 Years		>=65 Years	
Timepoint **Data Category** **Statistic**	**Placebo (N=110)**	**mRNA-1273 (N=107)**	**Placebo (N=20)**	**mRNA-1273 (N=23)**

[d] Number of subjects meeting the criterion at the time point. Percentages are based on N1.

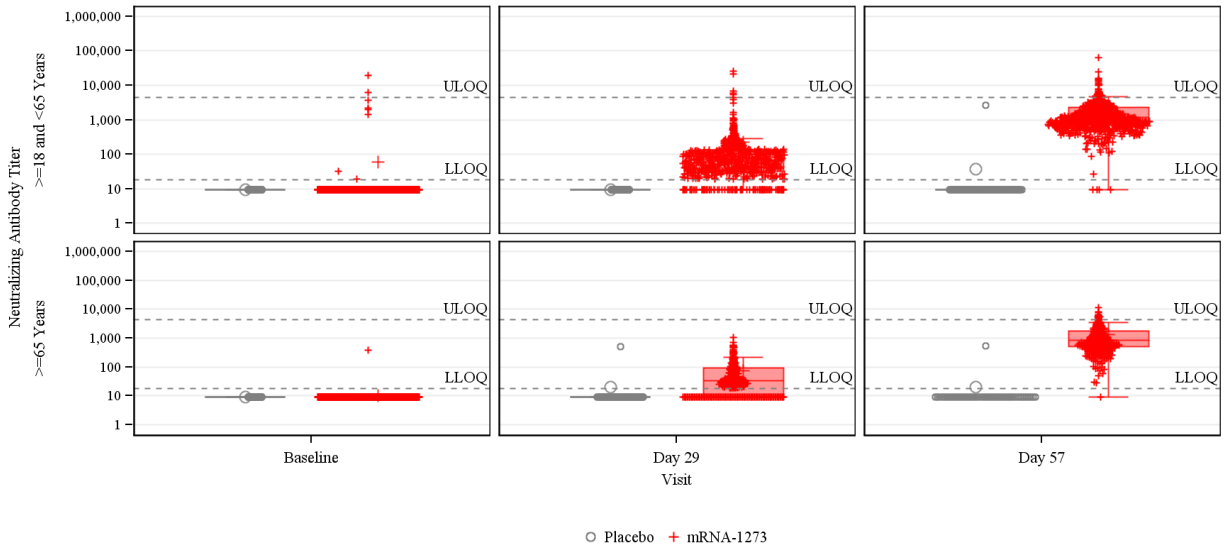
[e] 95% CI is calculated using the Clopper-Pearson method.

[f] >= z-fold increase from baseline at participant level is defined as a >= z x LLOQ for participants with baseline antibody titer below LLOQ, or a z-times or higher titer ratio in participants with baseline antibody titer equal to or above the LLOQ.

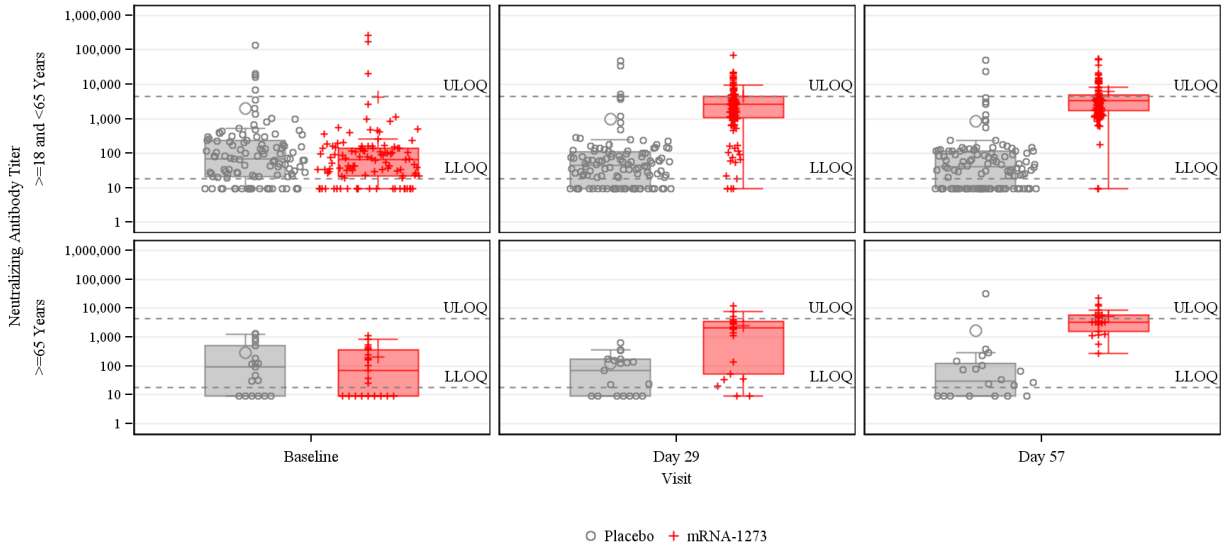
Source: Table 14.2.4.2.1.4.1.

Figure 6-8: Box Plot of Pseudovirus Neutralizing Antibody ID_{50} titers Neutralizing Specific to SARS-CoV-2 S-Protein by Pseudotyped Virus Neutralization Assay by Baseline SARS-CoV-2 Status and Age Group (Per-Protocol Random Subcohort for Immunogenicity)

Baseline SARS-CoV-2 Status: negative
Antibody: Pseudovirus Neutralizing Antibody ID_{50} Titers (LLOQ: 18.5, ULOQ: 4404)



Baseline SARS-CoV-2 Status: positive
Antibody: Pseudovirus Neutralizing Antibody ID_{50} Titers (LLOQ: 18.5, ULOQ: 4404)



Antibody values reported as below the lower limit of quantification (LLOQ) are replaced by 0.5 x LLOQ. Values greater than the upper limit of quantification (ULOQ) are replaced by ULOQ if actual values are not available.

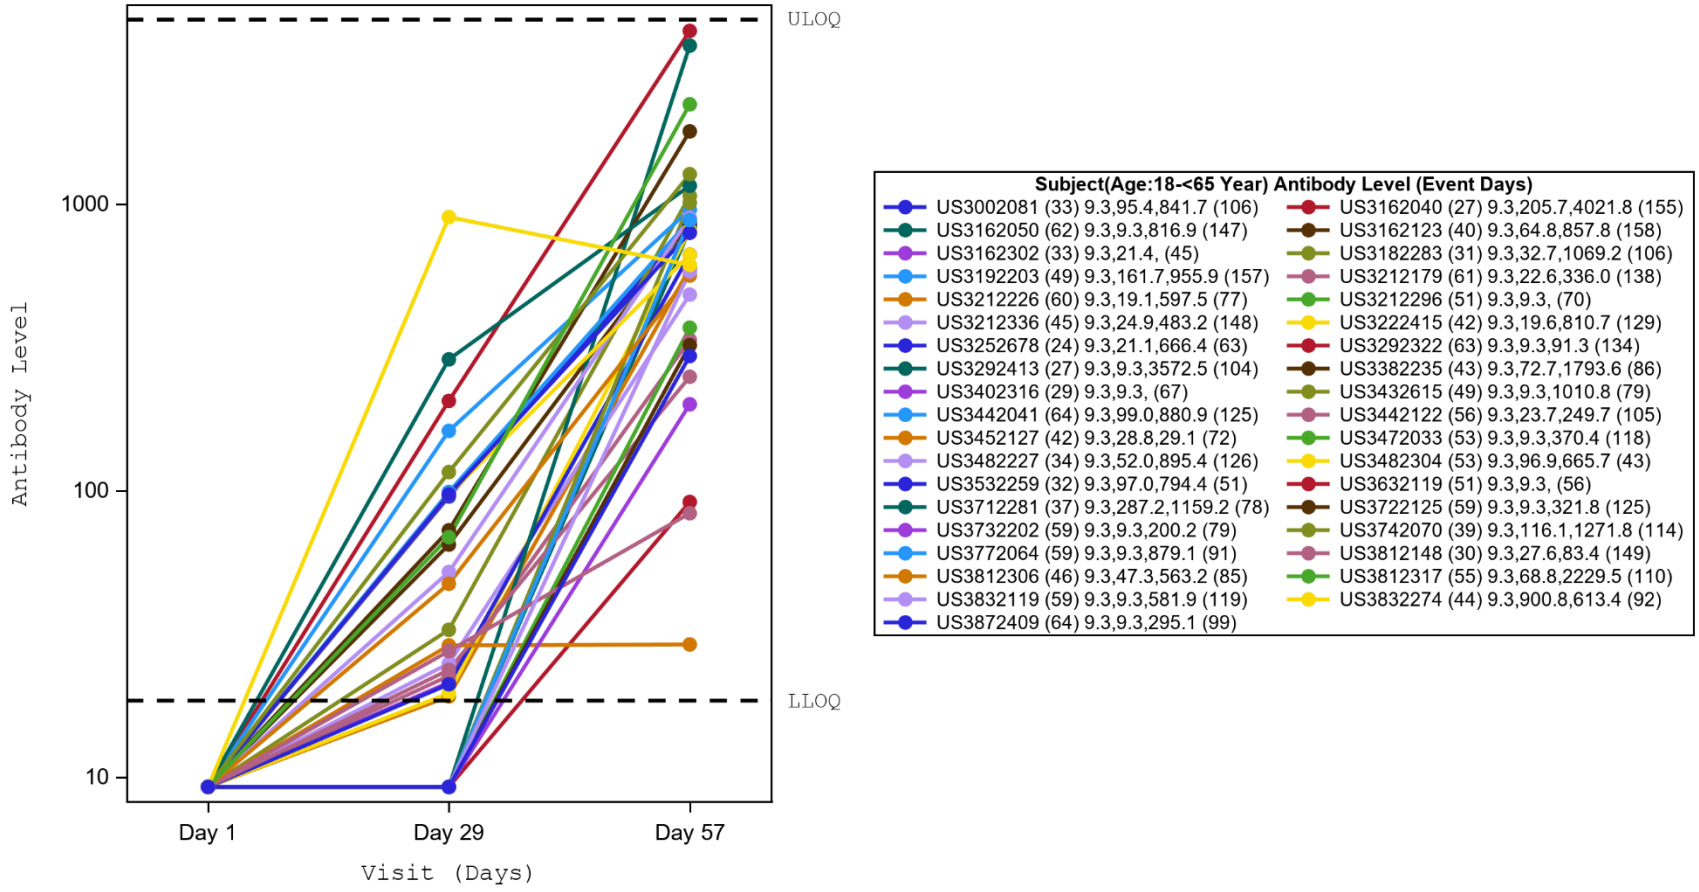
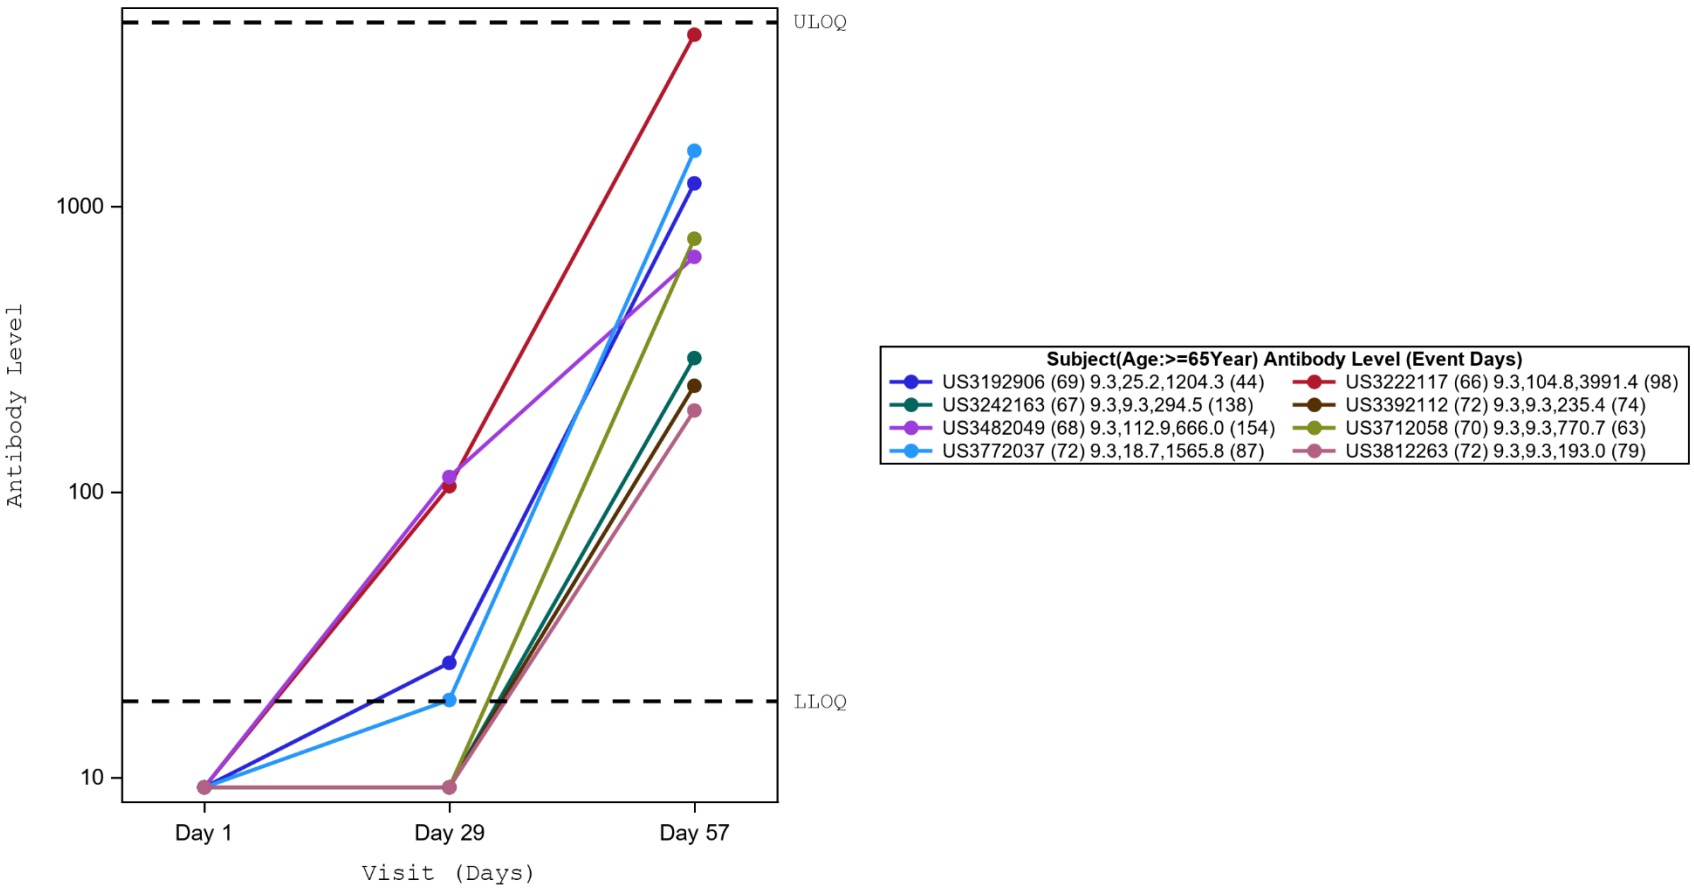
6.5.2 Analysis of Breakthrough COVID-19 Cases

Available nAb data in mRNA-1273 participants who were adjudicated COVID-19 cases starting 14 days after second injection in the PP Set are presented in Figure 6-9. These results appeared similar to those for the overall study population (Figure 6-7). Results for bAb levels as measured by MSD or ELISA assay are presented in Section 14 (Figure 16.2.2.1.3.1.1.3 and Figure 16.2.2.1.3.1.1.4, respectively).

Overall, while vaccination with mRNA-1273 was highly immunogenic and protective against COVID-19, breakthrough cases occurred and there was no apparent bAb level or nAb titer through Day 57 that was predictive of the presence or absence of breakthrough COVID-19 cases.

Figure 6-9: Plot of Pseudovirus Neutralizing Antibody ID_{50} in Participants on mRNA-1273 with COVID-19* Based on Adjudication Committee Assessments Starting 14 Days After Second Injection (Per-Protocol Set)





COVID-19 cases with corresponding immunogenicity data available

* with the censoring rules for efficacy analyses. COVID-19 case is based on eligible symptoms and positive RT-PCR within 14 days. If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys.

6.8 By-Participant Displays

By-participant displays are in Appendix 16.2.

6.9 Efficacy Conclusions

6.9.1 Primary Efficacy Conclusions

The primary efficacy endpoint was VE of mRNA-1273 to prevent the first occurrence of adjudicated COVID-19 starting 14 days after the second injection of IP in the PP Set.

The final efficacy analysis of the primary endpoint for Part A (04 May 2021) included 799 cases. The results of this analysis were consistent with the results of the interim and primary efficacy analyses, confirming persistent, high efficacy over a substantially larger case database over a longer median observation period of over 5.3 months. For the final efficacy analysis, the VE point estimate was 93.2% ($p < 0.0001$) and within the 95% CIs of the VE point estimates for the interim and primary efficacy analyses.

- Divergence of case incidence began early between mRNA-1273 and placebo groups, starting in the period from randomization up to 14 days after the first injection. Thereafter, cumulative incidence rate for the placebo group increased steadily while it remained stable and low in the mRNA-1273 group for the remainder of the observation period.
- Vaccine efficacy was consistent across subgroups for the primary efficacy endpoint.

6.9.2 Secondary Efficacy Conclusions

The VE of mRNA-1273 to prevent adjudicated severe COVID-19 cases starting 14 days after second injection was consistent with the VE for the primary endpoint and was numerically higher than the VE for the primary endpoint.

- For the final analysis of efficacy for Part A, 108 participants had adjudicated severe COVID-19 starting 14 days after second injection in the PP Set (106 cases in the placebo group and 2 cases in the mRNA-1273 group); the VE point estimate based on the hazard ratio was 98.2%, confirming and extending the primary analysis of 25 Nov 2020 based on more than 3 times as many cases accrued over an approximately 2 times longer period of observation.
- Divergence of case incidence of severe COVID-19 began early between mRNA-1273 and placebo groups, starting in the period from 7 to 14 days after the first injection.
- Subgroup analyses were consistent with the primary analysis of efficacy and the point estimates of efficacy remained very high. Consistent VE point estimates were observed in subgroup analyses of participants with 1 risk factor, at least 2 risk factors, chronic lung disease, significant cardiac disease, severe obesity, diabetes, liver disease, and HIV infection.

The VE of mRNA-1273 to prevent SARS-CoV-2 infection, regardless of COVID-19 symptomatology and severity, starting 14 days after second injection was consistent with the VE for the primary endpoint.

- Including the RT-PCR and Elecsys results from the PDV, a total of 1,619 participants had a SARS-CoV-2 infection starting 14 days after second injection in the PP Set (1,339 cases in the placebo group and 280 cases in the mRNA-1273 group); the VE point estimate based on the hazard ratio was 82.0%.
- Compared to the primary endpoint analyses, there were similar early onset of divergence in case incidence between treatment groups and similar stable and low rate of incidence rate for mRNA-1273 with increasing incidence rate in the placebo group.
- There were consistent, high VE point estimates across subgroups.

For the less restrictive secondary definition of COVID-19, the VE of mRNA-1273 was consistent with the VE for the primary endpoint, indicating that mRNA-1273 is efficacious even against mild COVID-19.

The VE to prevent asymptomatic SARS-CoV-2 infection was analyzed in the PP Set, including the RT-PCR and Elecsys results from the PDV, based on a total of 712 participants who had an asymptomatic SARS-CoV-2 infection starting 14 days after randomization (498 cases in the placebo group and 214 cases in the mRNA-1273 group). The VE point estimate based on the hazard ratio was 63.0%. This analysis confirms that vaccination with mRNA-1273 protects against asymptomatic infection (albeit at a lower VE than for symptomatic cases).

6.9.3 Immunogenicity Conclusions

mRNA-1273 was highly immunogenic as measured by both bAb and nAb in both SARS-CoV-2 baseline-negative and baseline-positive individuals, as indicated by increased bAb and nAb levels 1 month after first injection (Day 29) and 1 month after second injection (Day 57).

Antibody levels at Day 29 in baseline-positive mRNA-1273 treated participants were similar to those observed at Day 57 in baseline-negative participants, indicating that the first injection of mRNA-1273 acts like a booster in participants with previous SARS-CoV-2 infection.

Among SARS-CoV-2 baseline-negative mRNA-1273 treated participants, seroresponse by bAb assay exceeded 99% at both Day 29 and Day 57, while seroresponse by nAb assay was 81.4% at Day 29 and 98.9% at Day 57.

Similar results were observed for subgroups stratified by age (≥ 18 to < 65 years and ≥ 65 years) in both SARS-CoV-2 baseline-negative and baseline-positive mRNA-1273 treated participants.

While vaccination with mRNA-1273 was highly immunogenic and protective against COVID-19, breakthrough cases occurred and there was no apparent bAb level or nAb titer through Day 57 that was predictive of the presence or absence of breakthrough COVID-19 cases.

7 SAFETY RESULTS

Safety analyses results are based on the final analysis of Part A based on a database lock of 04 May 2021, unless otherwise specified.

7.1 Solicited Adverse Reactions

Participants recorded solicited local and systemic ARs in the eDiary on the day of each IP injection and during the 7 days after each IP injection (Section 3.7.1.1). If ARs persisted beyond 7 days, the eDiary solicited entries until the ARs subsided.

7.1.1 Incidence and Severity of Solicited Adverse Reactions Starting Within 7 Days After Injection

Observations for solicited ARs were consistent with earlier clinical trials with the mRNA-1273 vaccine. Incidence of local and systemic ARs was higher in the mRNA-1273 group than in the placebo group, and in the mRNA-1273 group, incidence was higher after the second injection than after the first. Most solicited ARs were grade 1 to grade 2 in severity and the severity tended to increase after the second injection.

Incidence of solicited local ARs was higher in the mRNA-1273 group (84.2%) than in the placebo group (19.9%) after the first injection (Table 7-1) and after the second injection (88.7% in the mRNA-1273 group compared with 18.9% in the placebo group) (Table 7-2). Pain was the most commonly reported local AR in the mRNA-1273 group after both injections, and incidence was higher after the second injection (83.7% after the first injection and 88.3% after the second injection). In the mRNA-1273 group, grade 3 solicited local ARs were more common after the second injection (7.0%) than after the first (3.5%). Grade 3 local ARs occurred infrequently in the placebo group after either injection. Pain was the event most commonly reported grade 3 local AR in the mRNA-1273 group after both injections, and the incidence of grade 3 pain was higher after the second injection (2.7% after the first injection and 4.1% after the second injection). Grade 3 pain in the mRNA-1273 group was the only grade 3 solicited local AR reported at a frequency > 2% after either injection. No grade 4 solicited local ARs were reported.

Incidence of solicited systemic ARs was higher in the mRNA-1273 group (54.8%) than in the placebo group (42.2%) after the first injection (Table 7-1) and after the second injection (79.5% in the mRNA-1273 group compared with 36.7% in the placebo group) (Table 7-2). In the mRNA-1273 group, incidence of systemic ARs was higher after the second injection compared with after the first. In the mRNA-1273 group, fatigue (37.2%) and headache (32.6%) were the most commonly reported systemic ARs after the first and second injections (incidence was

higher for fatigue [65.4%] than for headache [58.8%]). Incidence was also higher for myalgia (58.1%), arthralgia (42.9%), and chills (44.3%) after the second injection (first injection incidence was 22.7%, 16.6%, and 8.3%, respectively). Fatigue and headache were the most commonly reported grade 3 systemic ARs in the mRNA-1273 group after the first injection (1.0% for fatigue and 1.8% for headache). This was also true after the second injection, and incidence of grade 3 fatigue (9.8%) or grade 3 headache (4.5%) were higher compared with the first injection. In addition, incidence of grade 3 myalgia (9.0%) and grade 3 arthralgia (5.3%) were higher compared with the first injection (0.6% for myalgia and 0.4% for arthralgia). In the placebo group, incidence and severity were generally not higher after the second injection compared with the first. At least one grade 4 solicited systemic AR was reported for 5 participants in the mRNA-1273 group (< 0.1%) and 6 participants in the placebo group (< 0.1%) after the first injection and for 14 (< 0.1%) and 3 (< 0.1%) participants, respectively, after the second injection. The most common grade 4 systemic AR was fever, defined as a temperature above 40°C, which was reported in 4 participants in the mRNA-1273 group and 6 participants in the placebo group after the first injection and for 13 and 3 participants, respectively, after the second injection.

Table 7-1: Summary of Participants With Solicited Adverse Reactions Starting Within 7 Days After First Injection by Grade (First Injection Solicited Safety Set)

Solicited Adverse Reaction Category Grade	Placebo (N=15151) n (%)	mRNA-1273 (N=15166) n (%)	Total (N=30317) n (%)
Solicited adverse reactions - N1	15151	15166	30317

Abbreviations: CI = confidence intervals; N1 = number of exposed subjects who submitted any data for the event.
Any = Grade 1 or higher.
Percentages are based on the number of exposed subjects who submitted any data for the event (N1).

Solicited Adverse Reaction Category Grade	Placebo (N=15151) n (%)	mRNA-1273 (N=15166) n (%)	Total (N=30317) n (%)

95% CI is calculated using the Clopper-Pearson method.

Severity grading for solicited adverse reactions is based on modified Toxicity Grading Scale for Healthy Adult and Adolescent Volunteers Enrolled in Preventative Vaccine Clinical Trials (DHHS 2007).

Pain: Grade 3 = any use of prescription pain reliever/prevents daily activity; Grade 4 = requires emergency room visit or hospitalization

Erythema and Swelling: Grade 3 = >100mm/>10cm; Grade 4 = necrosis or exfoliative dermatitis.

Axillary Swelling or Tenderness: Grade 3 = any use of prescription (narcotic) pain reliever or prevents daily activity; Grade 4 = requires emergency room visit or hospitalization.

Fever: Grade 3 = ≥39.0 – ≤40.0°C or ≥102.1 – ≤104.0°F; Grade 4: > 40.0°C or > 104.0°F.

Headache: Grade 3 = significant; any use of prescription pain reliever or prevents daily activity; Grade 4 = requires emergency room visit or hospitalization

Fatigue, Myalgia, and Arthralgia: Grade 3 = significant; prevents daily activity; Grade 4 = requires emergency room visit or hospitalization.

Nausea/Vomiting: Grade 3 = prevents daily activity, requires outpatient intravenous hydration; Grade 4 = requires emergency room visit or hospitalization for hypotensive shock.

Chills: Grade 3 = prevents daily activity and requires medical intervention; Grade 4 = requires emergency room visit or hospitalization.

Abbreviations: CI = confidence intervals; N1 = number of exposed subjects who submitted any data for the event.
Any = Grade 1 or higher.

Solicited Adverse Reaction Category Grade	Placebo (N=14578) n (%)	mRNA-1273 (N=14691) n (%)	Total (N=29269) n (%)

Percentages are based on the number of exposed subjects who submitted any data for the event (N1).

95% CI is calculated using the Clopper-Pearson method.

Severity grading for solicited adverse reactions is based on modified Toxicity Grading Scale for Healthy Adult and Adolescent Volunteers Enrolled in Preventative Vaccine Clinical Trials (DHHS 2007).

Pain: Grade 3 = any use of prescription pain reliever/prevents daily activity; Grade 4 = requires emergency room visit or hospitalization

Erythema and Swelling: Grade 3 = >100mm/>10cm; Grade 4 = necrosis or exfoliative dermatitis.

Axillary Swelling or Tenderness: Grade 3 = any use of prescription (narcotic) pain reliever or prevents daily activity; Grade 4 = requires emergency room visit or hospitalization.

Fever: Grade 3 = ≥39.0 – ≤40.0°C or ≥102.1 – ≤104.0°F; Grade 4: > 40.0°C or > 104.0°F.

Headache: Grade 3 = significant; any use of prescription pain reliever or prevents daily activity; Grade 4 = requires emergency room visit or hospitalization

Fatigue, Myalgia, and Arthralgia: Grade 3 = significant; prevents daily activity; Grade 4 = requires emergency room visit or hospitalization.

Nausea/Vomiting: Grade 3 = prevents daily activity, requires outpatient intravenous hydration; Grade 4 = requires emergency room visit or hospitalization for hypotensive shock.

Chills: Grade 3 = prevents daily activity and requires medical intervention; Grade 4 = requires emergency room visit or hospitalization.

Source: Table 14.3.1.1.1.2.

7.1.2 Onset of Solicited Adverse Reactions

Onset of solicited local and systemic ARs was mostly within the first 2 days after either injection. Local ARs most commonly had onset within the first day after either injection (in the mRNA-1273 group, 42.3% of participants after the first injection [Table 14.3.1.3.1.1] and 54.8% after the second injection [Table 14.3.1.3.1.2]). This was largely driven by findings for pain, which was the most commonly reported local AR. Systemic ARs most commonly had onset on Day 2 after the second injection (42.3% of participants in the mRNA-1273 group); after the first injection, onset was common on Day 1 (20.0%) and on Day 2 (18.4%). This was largely driven by findings for fatigue and headache, which were the most commonly reported systemic ARs.

7.1.3 Duration (Number of Days) of Solicited Adverse Reactions

The duration was calculated as the cumulative number of days that the solicited AR was reported, including the day of injection.

The solicited ARs in participants who received mRNA-1273 persisted for a median of 1 to 3 days after the first and second injection (Table 7-3 and Table 7-4), with no apparent difference noted between the first and second injection. Grade 3 solicited systemic ARs generally persisted for a median of 1 to 4 days, and median duration was generally similar after the first and second

injection (Table 14.3.1.4.4.1 and Table 14.3.1.4.4.2). The few grade 4 ARs reported after the first and second injection resolved within 7 days after injection.

The median duration of solicited local ARs ranged from 1 to 2 days in both the mRNA-1273 and placebo groups after the first injection (Table 7-3) and ranged from 2 to 3 days in the mRNA-1273 group vs. 1 day for all local ARs in the placebo group after the second injection (Table 7-4). In the mRNA-1273 group, with the exception of pain, the median duration of grade 3 solicited local ARs was slightly longer after the second injection (Table 14.3.1.4.4.1 and Table 14.3.1.4.4.2). No grade 4 solicited local ARs were reported after the first and second injection (Table 14.3.1.4.5.1 and Table 14.3.1.4.5.2).

The median duration of solicited systemic ARs ranged from 1 to 2 days in both mRNA-1273 and placebo groups after the first injection (Table 7-3) and after the second injection (Table 7-4). In the mRNA-1273 group, the median duration of grade 3 solicited systemic AR of nausea/vomiting was 1 day after the first injection and 3 days after the second injection; no other differences were noted for solicited systemic ARs between the first and second injections (Table 14.3.1.4.4.1 and Table 14.3.1.4.4.2). Grade 4 solicited systemic ARs were reported in both the mRNA-1273 and placebo groups after the first and second injection; all grade 4 solicited systemic ARs resolved within 7 days after injection (Table 14.3.1.4.5.1 and Table 14.3.1.4.5.2).

n = Number of exposed subjects who reported the event on any day within 7 days of the second injection.

Number of days is calculated as the days of the solicited adverse reaction reported within the 7 days of injection including the day of injection. If the solicited AR continues beyond 7 days, the consecutive days a solicited adverse reaction is reported after 7 days are included.

Source: Table 14.3.1.4.1.2.

7.1.3.1 Solicited Adverse Reactions Persisting Beyond 7 Days After Injection

Among solicited ARs that persisted beyond 7 days after the first injection, solicited local ARs were reported for 2.4% of participants in the mRNA-1273 group and 0.9% of participants in the placebo group, and solicited systemic ARs were reported for 5.7% and 5.6% of participants, respectively (Table 14.3.1.6.1.1). Findings were similar after the second injection (Table 14.3.1.6.1.2).

Most local and systemic solicited ARs that persisted beyond 7 days were grade 1 or 2 in severity after either injection. Grade 3 persistent solicited local ARs were reported for 22 participants (0.1%) in the mRNA-1273 group and 4 participants (< 0.1%) in the placebo group after the first injection; incidence was higher in the mRNA-1273 group (67 participants [0.5%]) after the second injection. Grade 3 persistent systemic ARs were reported for 97 participants in the mRNA-1273 group and 91 participants in the placebo group (0.6% each); incidence was higher in the mRNA-1273 group (231 participants [1.6%]) after the second injection. No grade 4 persistent solicited ARs were reported after either injection.

Axillary swelling or tenderness and pain were the most commonly reported persistent local ARs; axillary swelling or tenderness was more common after the first injection and pain was more common after the second. No individual solicited local AR term appeared more likely than others to occur at grade 3 after either injection.

Fatigue and headache were the most commonly reported persistent solicited systemic ARs after either injection. Persistent fever was rarely reported, occurring in only 7 participants (< 0.1%) after the first injection and 3 participants (< 0.1%) after the second injection. No individual solicited systemic AR term appeared more likely than others to occur at grade 3 after the first injection. After the second injection, fatigue was more commonly reported as a grade 3 persistent

solicited AR than other events (1.0% of participants in the mRNA-1273 group and 0.4% of participants in the placebo group).

7.1.3.2 Local Adverse Reaction With Delayed Onset Beyond 7 Days After Injection

Few participants (≤ 3.4%) in both groups had local ARs that started beyond 7 days after either injection (Table 7-5). For most participants in both groups who reported local ARs after Day 7 after either injection, the reaction had begun within the first 7 days after the injection and was still ongoing. A local AR that occurred within the first 7 days but restarted on Day 8 or later was reported for 83 participants (0.5%) in the mRNA-1273 group after the first injection and for 38 participants (0.3%) after the second injection.

In the mRNA-1273 group, the incidence of local AR with delayed onset (AR started on Day 8 or afterwards) was higher after the first injection (80 participants [0.5%]) than after the second injection (10 participants [< 0.1%]) (Table 7-5). The most common AR that was first reported on Day 8 or later was erythema, which was reported for 68 participants (0.4%) in the mRNA-1273 group after the first injection and 6 additional participants (< 0.1%) in the mRNA-1273 group after the second injection.

Table 7-5: Summary of Participants With Local Adverse Reactions That Occurs at Day 8 or Beyond of Each Injection (Solicited Safety Set)

Category	Vaccination 1		Vaccination 2	
	Placebo (N=15151) n (%)	mRNA-1273 (N=15166) n (%)	Placebo (N=14578) n (%)	mRNA-1273 (N=14691) n (%)
Subjects with any local adverse reactions occurs at day 8 or beyond	158 (1.0)	514 (3.4)	199 (1.4)	356 (2.4)
Started within 7-day of the injection and continuing beyond 7 days	130 (0.9)	351 (2.3)	122 (0.8)	308 (2.1)
Had solicited AR within 7 days, and re-started on day 8 or afterwards	10 (<0.1)	83 (0.5)	20 (0.1)	38 (0.3)
No solicited AR within 7 days, and had AR started on day 8 or afterwards	18 (0.1)	80 (0.5)	57 (0.4)	10 (<0.1)
Subjects with pain occurs at day 8 or beyond	70 (0.5)	156 (1.0)	116 (0.8)	186 (1.3)
Started within 7-day of the injection and continuing beyond 7 days	56 (0.4)	102 (0.7)	58 (0.4)	155 (1.1)
Had solicited AR within 7 days, and re-started on day 8 or afterwards	6 (<0.1)	53 (0.3)	17 (0.1)	31 (0.2)
No solicited AR within 7 days, and had AR started on day 8 or afterwards	8 (<0.1)	1 (<0.1)	41 (0.3)	0
Subjects with erythema (redness) occurs at day 8 or beyond	27 (0.2)	117 (0.8)	21 (0.1)	78 (0.5)
Started within 7-day of the injection and continuing beyond 7 days	20 (0.1)	34 (0.2)	13 (<0.1)	70 (0.5)
Had solicited AR within 7 days, and re-started on day 8 or afterwards	0	15 (<0.1)	0	2 (<0.1)
No solicited AR within 7 days, and had AR started on day 8 or afterwards	7 (<0.1)	68 (0.4)	8 (<0.1)	6 (<0.1)
Subjects with swelling (hardness) occurs at day 8 or beyond	25 (0.2)	88 (0.6)	22 (0.2)	76 (0.5)
Started within 7-day of the injection and continuing beyond 7 days	22 (0.1)	33 (0.2)	16 (0.1)	70 (0.5)
Had solicited AR within 7 days, and re-started on day 8 or afterwards	0	19 (0.1)	0	2 (<0.1)
No solicited AR within 7 days, and had AR started on day 8 or afterwards	3 (<0.1)	36 (0.2)	6 (<0.1)	4 (<0.1)
Subjects with axillary swelling or tenderness occurs at day 8 or beyond	62 (0.4)	243 (1.6)	57 (0.4)	101 (0.7)
Started within 7-day of the injection and continuing beyond 7 days	54 (0.4)	223 (1.5)	48 (0.3)	90 (0.6)

Category	Vaccination 1		Vaccination 2	
	Placebo (N=15151) n (%)	mRNA-1273 (N=15166) n (%)	Placebo (N=14578) n (%)	mRNA-1273 (N=14691) n (%)
Had solicited AR within 7 days, and re-started on day 8 or afterwards	5 (<0.1)	12 (<0.1)	4 (<0.1)	7 (<0.1)
No solicited AR within 7 days, and had AR started on day 8 or afterwards	3 (<0.1)	8 (<0.1)	5 (<0.1)	4 (<0.1)

Abbreviation: AR = adverse reaction.

Subjects with adverse reactions on Day 8 or beyond, independent of the start date.

Source: Table 14.3.1.21.1.4.

7.1.4 Solicited Adverse Reactions by Subgroup

7.1.4.1 Age Groups

Incidence of solicited local and systemic ARs after either injection in the mRNA-1273 group was lower among older adults (≥ 65 years) than among younger adults (≥ 18 to < 65 years) (Table 7-6 and Table 7-7), but within both age subgroups, findings were similar to those for the overall population (Section 7.1.1).

No differences were apparent between the age subgroups for duration of solicited local or systemic ARs after the first (Table 14.3.1.4.2.1) or second (Table 14.3.1.4.2.2) injections.

Table 7-6: Summary of Participants With Solicited Adverse Reactions Starting Within 7 Days After First Injection by Age Group and Grade (First Injection Solicited Safety Set)

Solicited Adverse Reaction Category Grade	Placebo (N=11402) n (%)	mRNA-1273 (N=11406) n (%)	Total (N=22808) n (%)

CI = Confidence intervals. N1 = Number of exposed subjects who submitted any data for the event. Any = Grade 1 or higher.

Percentages are based on the number of exposed subjects who submitted any data for the event (N1).

95% CI is calculated using the Clopper-Pearson method.

Severity grading for solicited adverse reactions is based on modified Toxicity Grading Scale for Healthy Adult and Adolescent Volunteers Enrolled in Preventative Vaccine Clinical Trials (DHHS 2007).

Pain: Grade 3 = any use of prescription pain reliever/prevents daily activity; Grade 4 = requires emergency room visit or hospitalization.

Erythema and Swelling: Grade 3 = >100mm/>10cm; Grade 4 = necrosis or exfoliative dermatitis.

Solicited Adverse Reaction Category Grade	Placebo (N=3749) n (%)	mRNA-1273 (N=3760) n (%)	Total (N=7509) n (%)

Axillary Swelling or Tenderness: Grade 3 = any use of prescription (narcotic) pain reliever or prevents daily activity; Grade 4 = requires emergency room visit or hospitalization.

Fever: Grade 3 = ≥39.0 – ≤40.0°C or ≥102.1 – ≤104.0°F; Grade 4: > 40.0°C or > 104.0°F.

Headache: Grade 3 = significant; any use of prescription pain reliever or prevents daily activity; Grade 4 = requires emergency room visit or hospitalization.

Fatigue, Myalgia, and Arthralgia: Grade 3 = significant; prevents daily activity; Grade 4 = requires emergency room visit or hospitalization.

Nausea/Vomiting: Grade 3 = prevents daily activity, requires outpatient intravenous hydration; Grade 4 = requires emergency room visit or hospitalization for hypotensive shock.

Chills: Grade 3 = prevents daily activity and requires medical intervention; Grade 4 = requires emergency room visit or hospitalization.

CI = Confidence intervals. N1 = Number of exposed subjects who submitted any data for the event. Any = Grade 1 or higher.

Percentages are based on the number of exposed subjects who submitted any data for the event (N1).

95% CI is calculated using the Clopper-Pearson method.

Severity grading for solicited adverse reactions is based on modified Toxicity Grading Scale for Healthy Adult and Adolescent Volunteers Enrolled in Preventative Vaccine Clinical Trials (DHHS 2007).

Pain: Grade 3 = any use of prescription pain reliever/prevents daily activity; Grade 4 = requires emergency room visit or hospitalization.

Erythema and Swelling: Grade 3 = >100mm/>10cm; Grade 4 = necrosis or exfoliative dermatitis.

Solicited Adverse Reaction Category Grade	Placebo (N=3649) n (%)	mRNA-1273 (N=3691) n (%)	Total (N=7340) n (%)

Axillary Swelling or Tenderness: Grade 3 = any use of prescription (narcotic) pain reliever or prevents daily activity; Grade 4 = requires emergency room visit or hospitalization.

Fever: Grade 3 = ≥39.0 – ≤40.0°C or ≥102.1 – ≤104.0°F; Grade 4: > 40.0°C or > 104.0°F.

Headache: Grade 3 = significant; any use of prescription pain reliever or prevents daily activity; Grade 4 = requires emergency room visit or hospitalization.

Fatigue, Myalgia, and Arthralgia: Grade 3 = significant; prevents daily activity; Grade 4 = requires emergency room visit or hospitalization.

Nausea/Vomiting: Grade 3 = prevents daily activity, requires outpatient intravenous hydration; Grade 4 = requires emergency room visit or hospitalization for hypotensive shock.

Chills: Grade 3 = prevents daily activity and requires medical intervention; Grade 4 = requires emergency room visit or hospitalization.

Source: Table 14.3.1.1.2.1.2.

7.1.4.2 Baseline SARS-CoV-2 Status

Baseline SARS-CoV-2 status was negative for most participants. Results among participants with negative baseline status reflect those of the overall population.

Among participants with baseline SARS-CoV-2 positive status in the mRNA-1273 group, the percentage of participants who reported a grade 3 solicited local or systemic AR after the first injection was 8.4% (29/346) (Table 7-8); the percentage in the overall population was 5.6% (849/15166) (Table 7-1). This was largely driven by grade 3 solicited systemic ARs, which were reported for 6.6% (23/346) among those with positive baseline status (Table 7-8) compared with 3.0% (449/15166) for the overall mRNA-1273 group (Table 7-1). In the mRNA-1273 group, the percentages of participants with positive baseline status who had grade 3 events were higher for all systemic ARs compared with the percentages in the overall group. These differences were not observed after the second injection (Table 7-9).

No differences were apparent for this subgroup in duration of local or systemic ARs after the first (Table 14.3.1.4.3.1) or second (Table 14.3.1.4.3.2) injections or for ARs persisting beyond 7 days after the first (Table 14.3.1.6.3.1) or second (Table 14.3.1.6.3.2) injections.

Table 7-8: Summary of Participants With Solicited Adverse Reactions Starting Within 7 Days After First Injection by Baseline SARS-CoV-2 Status and Grade (First Injection Solicited Safety Set)

CI = Confidence intervals. N1 = Number of exposed subjects who submitted any data for the event. Any = Grade 1 or higher.

Percentages are based on the number of exposed subjects who submitted any data for the event (N1).

95% CI is calculated using the Clopper-Pearson method.

Severity grading for solicited adverse reactions is based on modified Toxicity Grading Scale for Healthy Adult and Adolescent Volunteers Enrolled in Preventative Vaccine Clinical Trials (DHHS 2007).

Pain: Grade 3 = any use of prescription pain reliever/prevents daily activity; Grade 4 = requires emergency room visit or hospitalization

Erythema and Swelling: Grade 3 = >100mm/>10cm; Grade 4 = necrosis or exfoliative dermatitis.

Solicited Adverse Reaction Category Grade	Placebo (N=84) n (%)	mRNA-1273 (N=87) n (%)	Total (N=171) n (%)

Axillary Swelling or Tenderness: Grade 3 = any use of prescription (narcotic) pain reliever or prevents daily activity; Grade 4 = requires emergency room visit or hospitalization.

Fever: Grade 3 = ≥39.0 – ≤40.0°C or ≥102.1 – ≤104.0°F; Grade 4: > 40.0°C or > 104.0°F.

Headache: Grade 3 = significant; any use of prescription pain reliever or prevents daily activity; Grade 4 = requires emergency room visit or hospitalization

Fatigue, Myalgia, and Arthralgia: Grade 3 = significant; prevents daily activity; Grade 4 = requires emergency room visit or hospitalization.

Nausea/Vomiting: Grade 3 = prevents daily activity, requires outpatient intravenous hydration; Grade 4 = requires emergency room visit or hospitalization for hypotensive shock.

Chills: Grade 3 = prevents daily activity and requires medical intervention; Grade 4 = requires emergency room visit or hospitalization.

CI = Confidence intervals. N1 = Number of exposed subjects who submitted any data for the event. Any = Grade 1 or higher.

Percentages are based on the number of exposed subjects who submitted any data for the event (N1).

95% CI is calculated using the Clopper-Pearson method.

Severity grading for solicited adverse reactions is based on modified Toxicity Grading Scale for Healthy Adult and Adolescent Volunteers Enrolled in Preventative Vaccine Clinical Trials (DHHS 2007).

Pain: Grade 3 = any use of prescription (narcotic) pain reliever/prevents daily activity; Grade 4 = requires emergency room visit or hospitalization

Erythema and Swelling: Grade 3 = >100mm/>10cm; Grade 4 = necrosis or exfoliative dermatitis.

Solicited Adverse Reaction Category Grade	Placebo (N=78) n (%)	mRNA-1273 (N=81) n (%)	Total (N=159) n (%)

Axillary Swelling or Tenderness: Grade 3 = any use of prescription pain reliever or prevents daily activity; Grade 4 = requires emergency room visit or hospitalization.

Fever: Grade 3 = ≥39.0 – ≤40.0°C or ≥102.1 – ≤104.0°F; Grade 4: > 40.0°C or > 104.0°F.

Headache: Grade 3 = significant; any use of prescription pain reliever or prevents daily activity; Grade 4 = requires emergency room visit or hospitalization

Fatigue, Myalgia, and Arthralgia: Grade 3 = significant; prevents daily activity; Grade 4 = requires emergency room visit or hospitalization.

Nausea/Vomiting: Grade 3 = prevents daily activity, requires outpatient intravenous hydration; Grade 4 = requires emergency room visit or hospitalization for hypotensive shock.

Chills: Grade 3 = prevents daily activity and requires medical intervention; Grade 4 = requires emergency room visit or hospitalization.

Source: Table 14.3.1.1.3.2.

7.1.4.3 Race and Ethnicity

In the Safety Set, race was reported as white for 79.2% of participants overall, Black or African American for 10.2%, Asian for 4.6%, and multiracial for 2.1%; no other category was reported for > 2% of participants (Table 14.1.3.2.2). Ethnicity was reported as Not Hispanic or Latino for 78.6% of participants overall. Results among participants who reported white race and those who reported Not Hispanic or Latino ethnicity reflect those of the overall population.

Compared with those who reported white race, participants who reported Black or African American race appeared to have lower incidence of solicited local ARs overall and for all reactions except axillary swelling or tenderness after the first injection, while incidence of systemic ARs appeared to be similar between the subgroups (Table 14.3.1.1.4.1). After the second injection, participants who reported Black or African American race appeared to have lower incidence of local and systemic ARs compared with those who reported White race (Table 14.3.1.1.4.2). Other subgroups by race were too small for meaningful comparison.

No relevant differences were observed in the incidence of local or systemic ARs between participants who reported ethnicity as Not Hispanic or Latino and those who reported Hispanic or Latino ethnicity after the first (Table 14.3.1.1.5.1) or second (Table 14.3.1.1.5.2) injection.

7.1.4.4 Sex

After both the first (Table 14.3.1.1.7.1) and second (Table 14.3.1.1.7.2) injections, female participants appeared to have higher incidence of local and systemic ARs compared with male participants.

7.1.5 Medication Use for Solicited Adverse Reactions of Pain and Fever

To further characterize potential reactogenicity of mRNA-1273, analyses were performed for participant use of medications to prevent or treat pain or fever. This analysis was based on participant-recorded use in the eDiary, wherein participants entered responses in the eDiary to questions about use of medications to treat or prevent pain or fever.

After the first injection, the use of medication for pain or fever was reported for 22.0% of participants in the mRNA-1273 group and 13.2% of participants in the placebo group (Table 7-10). After the second injection, the use of medication for pain or fever was higher in the mRNA-1273 group (53.5%) compared with after the first injection, while no notable difference was observed in the placebo group (10.9%) (Table 7-11). For most participants, the medication was used to treat, rather than to prevent, pain or fever. In the mRNA-1273 group after both injections, the percentage of participants who reported use of medication for pain or fever was higher in the ≥ 18 to < 65 years age group than that observed in the ≥ 65 years age group, which is consistent with the higher observed rate of reporting solicited ARs in the younger age cohort.

7.2 Unsolicited Adverse Events

Summaries of unsolicited adverse events are available for the 28-day post-injection follow-up period and with follow-up for the entire duration of Part A, which is the randomized, blinded part of the study. Summaries for Part A include all available participant level data up to early unblinding, study discontinuation, the Part B PDV or data cutoff date (26 Mar 2021), whichever was earlier, and provides accumulated safety data through a median duration of approximately 6 months after the second injection (Section 5.9).

7.2.1 Overview of Unsolicited Adverse Events

7.2.1.1 Up to 28 Days After Injection

The incidences of unsolicited TEAEs, severe TEAEs, and MAAEs regardless of relationship to the IP during the 28 days after any injection were generally similar in participants who received mRNA-1273 and those who received placebo (Table 7-12).

At least 1 TEAE that was assessed by the investigator to be treatment-related was reported in 13.6% and 8.2% of participants in the mRNA-1273 and placebo groups, respectively. These events were generally not severe and only rarely warranted discontinuation of treatment: the percentages of participants who had severe TEAEs that were assessed as treatment-related were 0.5% and 0.2%, respectively; and 20 and 14 participants, respectively, discontinued treatment in response to the event. Per protocol, solicited ARs were reported as treatment-related AEs if they started or were ongoing after 7 days after the injection, were SAEs or MAAEs, or resulted in discontinuation of treatment or withdrawal from the study (Section 3.7.4.1).

Table 7-12: Summary of Unsolicited Treatment Emergent Adverse Events up to 28 Days After Any Injection (Safety Set)

	Placebo (N=15162) n (%)	mRNA-1273 (N=15184) n (%)	Total (N=30346) n (%)
Unsolicited TEAEs regardless of relationship to study vaccination			
All	4338 (28.6)	4752 (31.3)	9090 (30.0)
Serious	104 (0.7)	98 (0.6)	202 (0.7)
Fatal	2 (<0.1)	2 (<0.1)	4 (<0.1)
Medically-attended	1940 (12.8)	1819 (12.0)	3759 (12.4)
Leading to discontinuation from study vaccine	92 (0.6)	61 (0.4)	153 (0.5)
Leading to discontinuation from participation in the study	6 (<0.1)	9 (<0.1)	15 (<0.1)

Unsolicited TEAEs related to study vaccination			
All	1236 (8.2)	2067 (13.6)	3303 (10.9)
Serious	3 (<0.1)	8 (<0.1)	11 (<0.1)
Fatal	0	0	0
Medically-attended	95 (0.6)	198 (1.3)	293 (1.0)
Leading to discontinuation from study vaccine	14 (<0.1)	20 (0.1)	34 (0.1)
Leading to discontinuation from participation in the study	0	1 (<0.1)	1 (<0.1)
Severe	31 (0.2)	83 (0.5)	114 (0.4)

A treatment-emergent adverse event (TEAE) is defined as any event not present before exposure to study vaccination or any event already present that worsens in intensity or frequency after exposure.

Percentages are based on the number of safety subjects.

Source: Table 14.3.1.7.1.1.

7.2.1.2 Overall Study Period in Part A

Per protocol (Protocol Section 8.3.6), TEAEs were collected to the end of the 28-day period, while SAEs, MAAEs, and TEAEs leading to study discontinued were collected throughout follow-up in Part A. Incidence of SAEs and MAAEs regardless of causality remained balanced between the groups with follow-up throughout Part A (Table 7-13). The incidence of MAAEs assessed by the investigator as related to investigational product in Part A was similar in each group to that observed in the 28-day period after each injection.

At least 1 unsolicited TEAE with a fatal outcome was reported for 17 participants in the mRNA-1273 group in Table 7-13, but death is reported for 16 participants in the mRNA-1273 group in Table 7-20. This apparent discrepancy is because there was 1 participant who had a TEAE with onset during Part A (before the PDV date and during the blinded portion) that had a fatal outcome during Part B (after unblinding at the PDV). The TEAE was first reported during Part A and its outcome is thus reported in Table 7-13, while the death, which did not occur until Part B, is not captured in Table 7-20.

Table 7-13: Summary of Unsolicited Treatment-Emergent Adverse Events in Part A (Safety Set)

	Placebo (N=15162) n (%)	mRNA-1273 (N=15184) n (%)	Total (N=30346) n (%)
Unsolicited TEAEs regardless of relationship to study vaccination

Severe	34 (0.2)	88 (0.6)	122 (0.4)

A treatment-emergent adverse event (TEAE) is defined as any event not present before exposure to study vaccination or any event already present that worsens in intensity or frequency after exposure.

Percentages are based on the number of safety subjects.

Source: Table 14.3.1.7.1.3.

7.2.2 Unsolicited Adverse Events by Preferred Term

The incidence of TEAEs was similar between the mRNA-1273 and placebo treatment groups in the 28-day follow-up period (31.3% and 28.6%, respectively [Table 7-12]) and in the full Part A follow-up period (41.6% and 43.0%, respectively [Table 7-13]). Unsolicited TEAEs are summarized by severity in Section 7.2.3 and by causality in Section 7.2.4. Unsolicited TEAEs with onset within 30 minutes of injection are summarized in Section 7.2.5.

The most commonly reported unsolicited TEAEs in the mRNA-1273 and placebo groups, respectively, were fatigue (5.0% vs. 4.4%) and headache (4.9% vs. 4.5%) during the 28-day follow-up period (Table 7-15) and during the Part A period (fatigue [5.8% vs. 5.3%] and headache [6.0% vs. 5.8%]) (Table 14.3.1.8.1.3).

Commonly reported adverse events were generally consistent with the solicited ARs captured to assess reactogenicity. During the 28-day follow-up period, unsolicited TEAEs that were reported for ≥ 1% of participants in the mRNA-1273 group and showed higher incidence compared with placebo were lymphadenopathy (1.7% vs. 0.8%), injection site pain (1.7% vs. 0.8%), and injection site erythema (1.0% vs. 0.3%). Other TEAEs that were reported for ≥ 1% of participants in the mRNA-1273 group and did not show higher incidence compared with the placebo group were arthralgia, myalgia, diarrhea, cough, nausea, oropharyngeal pain, nasal congestion, and hypertension (arthralgia, myalgia, and nausea were solicited systemic ARs and were only reported as TEAEs if they started on Day 8, or persisted after Day 7, after the most recent injection). Observations were similar with follow-up for the duration of Part A.

Rarer events that had a higher incidence in the mRNA-1273 group compared with the placebo group during the 28-day follow-up period included other varieties of injection site reactions and other events consistent with reactogenicity, such as injection site swelling, injection site pruritus, injection site lymphadenopathy, injection site induration, injection site macule, injection site urticaria, injection site rash, injection site papule, injection site warmth, pyrexia, and erythema (Table 14.3.1.8.1.1). Sinus headache and bursitis were also more commonly reported in the mRNA-1273 group than in the placebo group; some of the reports may have been associated with systemic ARs that have similar effects, such as headache and arthralgia, respectively. Observations were similar with follow-up for the duration of Part A, except that there was a larger number of different event terms that were reported for one or few participants (Table 14.3.1.8.1.3).

Assessment of TEAE incidence for other uncommon unsolicited TEAEs in the mRNA-1273 and placebo groups for clinically relevant differences involves evaluation of multiple comparisons without adjustment for multiplicity. Summary tables include rate ratios with 95% CIs as a descriptive measure to help review and were not a formal analysis to assess the difference.

Clinical plausibility has also not been taken into account with this analysis. Incidence was higher for some events in the mRNA-1273 group and for others in the placebo group, and this variation is likely attributable to chance.

Some events that had higher incidence in the placebo group, apparently by chance, are upper respiratory tract infection (82 participants [0.5%] in the mRNA-1273 group vs. 118 [0.8%] in the placebo group), basal cell carcinoma (10 [< 0.1%]) vs. 16 [0.1%]), seasonal allergy (33 [0.2%] vs. 47 [0.3%]), generalized anxiety disorder (0 vs. 4 [< 0.1%]), migraine (15 [< 0.1%] vs. 24 [0.2%]), presyncope (6 [< 0.1%] vs. 14 [< 0.1%]), sinus congestion (16 [0.1%] vs. 26 [0.2%]), abdominal discomfort (6 [< 0.1%] vs. 13 [< 0.1%]), contusion (20 [0.1%] vs. 29 [0.2%]), and procedural pain (18 [0.1%] vs. 31 [0.2%]) (Table 14.3.1.8.1.1). Some events that had higher incidence in the mRNA-1273 group, apparently by chance, are type 2 diabetes mellitus (21 [0.1%] vs. 11 [< 0.1%]), anxiety (52 [0.3%] vs. 38 [0.3%]), eye irritation (7 [< 0.1%] vs. 1 [< 0.1%]), respiratory tract congestion (18 [0.1%] vs. 7 [< 0.1%]), epistaxis (16 [0.1%] vs. 11 [< 0.1%]), gastroesophageal reflux disease (41 [0.3%] vs. 29 [0.2%]), abdominal pain (26 [0.2%] vs. 20 [0.1%]), and blood pressure diastolic increased (10 [< 0.1%] vs. 2 [< 0.1%]) (Table 14.3.1.8.1.1).

Review of Pericarditis and Myocarditis

In Part A, no cases of myocarditis were reported, and pericarditis was reported for 2 participants in the mRNA-1273 group and 2 participants in the placebo group (Table 14.3.1.8.1.3). The cases of pericarditis in the mRNA-1273 group occurred in (i) a 59-year old female who had nonserious chest pain, dyspnea, and fatigue on Day 4 post dose 2 that resolved within 2 days and subsequently presented with chest pain and syncope 68 days post dose 2 leading to hospitalization and a diagnosis of pericarditis and pericardial effusion, both of which resolved (the participant had received an influenza vaccination 1 month before the events), and (ii) a 65-year-old male hospitalized with a diagnosis of pericarditis 73 days post dose 2 which resolved the following day, and occurred 19 days after an SAE of myocardial infarction. These SAEs (including those in the placebo group) are described in Section 7.3.2.

Because myocarditis and pericarditis are typically rare events, Moderna assessed the clinical database for evidence of individual clinical symptoms that have been associated with these events. The randomized, blinded phase (Part A) data were assessed for TEAEs potentially associated with myocarditis or pericarditis. The TEAE data was assessed for any events mapping to PTs in the CDC working case definition diagnostic algorithm for probable and confirmed acute myocarditis and pericarditis. Using this approach, TEAEs were identified for the following 7 PTs: angina pectoris, chest discomfort, chest pain, musculoskeletal chest pain, dyspnea, palpitations, and syncope.

The TEAE database (collected for the 28 days after any injection) was assessed for the identified PTs, and the assessment further narrowed for those TEAEs occurring in temporal proximity to injection (within 7 days of any injection) based on the observed epidemiology of cases of myocarditis and pericarditis characterized from post-authorization data. As part of the study, the collection of unsolicited TEAE that are nonserious do not include narrative information but rather the verbatim entries regarding the event. All TEAEs were reviewed regardless of severity or causality (as determined by the investigator). Finally, the listing of participants reporting any of these PTs within 7 days of any injection was cross-checked to identify any participants reporting more than 1 of the targeted PT, reflecting constellations more suggestive of a possible diagnosis of myocarditis or pericarditis.

One participant reported more than 1 of the target PTs: a 71-year-old male in the mRNA-1273 group with relevant history of hyperlipidemia, hypertension, folate deficiency anemia, and constipation experienced 2 nonserious, mild, ongoing, and considered unrelated TEAEs on Days 2 and 4 post second dose, respectively, of "intermittent heart palpitations with exercising" and "intermittent chest discomfort with exercising type unknown" (verbatim terms). Other potentially relevant TEAEs reported for this participant within 7 days of these events were unrelated nonserious TEAEs of "fatigue," "generalized body aches in morning," "upper body muscle weakness," and "runny nose."

In the 28-day TEAE collection window, numerical imbalances between the mRNA-1273 and placebo groups were observed only for the PT chest pain (10 in the mRNA-1273 group and 5 in the placebo group; rate ratio 2.0 [95% CI: 0.71, 5.58]). Three of these chest pain events, all in the mRNA-1273 group, occurred within the 7-day window, one was considered related, and all resolved in 1 to 2 days. In the survey of the identified PTs in the 7-day window, imbalances in the reported PT (from the list described above) were observed for the following events:

- Dyspnea: 15 in the mRNA-1273 group and 3 in the placebo group
- Syncope: 7 in the mRNA-1273 group and 3 in the placebo group

For the PT dyspnea, 5 of the 15 events in the mRNA-1273 group were considered related, and all 18 dyspnea events resolved. For completeness, in addition to these dyspnea TEAEs, 5 participants (all in the mRNA-1273 group) reported dyspnea as an SAE, none of which were considered related and all of which occurred in participants > 50 years of age (these SAEs are described in Section 7.3.2).

For the PT syncope, 1 of the 7 events in the mRNA-1273 group was considered related, and all events resolved on the same day they occurred. For 1 of the 7 participants in the mRNA-1273 group, the syncope was an SAE: this 46-year-old Hispanic male had a previous medical history

of syncopal episodes, obesity, type 2 diabetes, and hypertension and was diagnosed with osteomyelitis during admission. The event syncope was considered not related to vaccine, and a transthoracic echocardiogram during admission showed normal cardiac function.

Overall, in this assessment of the targeted PTs, 1 participant manifested more than one of the identified PT within 7 days of any inoculation, and the events can reasonably be attributed to other comorbid conditions. For the imbalances observed for dyspnea and syncope in the 7-day window, most resolved quickly and did not cluster with other relevant TEAEs to suggest cases of myocarditis or pericarditis.

Investigation of events for which an apparent imbalance was observed or that were otherwise of interest did not suggest safety concerns with mRNA-1273, as described below.

Herpes Zoster

Incidence of herpes zoster during Part A of the study is shown in Figure 7-1. Incidence showed a larger imbalance (mRNA-1273 > placebo) over the full duration of Part A than during the 28-day follow-up period. No cases of herpes zoster were reported as SAEs, 1 case in the mRNA-1273 group was reported as severe (all other events were reported as mild or moderate), and all cases resolved, although 2 participants in the mRNA-1273 group also had events of post-herpetic neuralgia that were described as resolving.

Figure 7-1: Incidence of Herpes Zoster

Reported at any time during Part A: 73 participants	
mRNA-1273 TEAE: 50 (0.3%) MAAE: 40 (0.3%)	**Placebo** TEAE: 23 (0.2%) MAAE: 17 (0.1%)

Reported within the 28-day follow-up period after any dose: 37 participants	
mRNA-1273[1] TEAE: 22 (0.1%) (18 after Dose 1) MAAE: 17 (0.1%) Severe: 1 (< 0.1%)[2] Considered related: 2 (< 0.1%)	**Placebo** TEAE: 15 (< 0.1%) (9 after Dose 1) MAAE: 10 (< 0.1%)

Reported during Part A after the 28-day follow-up period:[3] 36 participants	
mRNA-1273 TEAE: 28 (0.1%) MAAE: 23 (0.1%)	**Placebo** TEAE: 8 (< 0.1%) MAAE: 7 (< 0.1%)

Abbreviations: MAAE = medically-attended adverse event; SAE = serious adverse event; TEAE = treatment-emergent adverse event.

1 One participant had vaccine discontinued due to herpes simplex (not included in these numbers for herpes zoster): A 44-year-old female had a moderate event reported on Day 6 after Dose 1. The event was not considered related to treatment and resolved on Day 18 (Listing 16.2.7.11).

2 A 61-year-old male had severe herpes zoster reported on Day 9 after Dose 1. The event was not considered related to treatment and resolved on Day 51 (Listing 16.2.7.7).

3 Per protocol, TEAEs were to be reported up to 28 days after any dose. After the 28-day follow-up period, only SAEs, MAAEs, and TEAEs leading to discontinuation were collected systematically.

Sources: Table 14.3.1.8.1.1, Table 14.3.1.8.1.3, Table 14.3.1.19.1.1, Table 14.3.1.19.1.3, Table 14.3.1.17.1.1, Table 14.3.1.11.1.1.

No microbiological confirmation of the presence of varicella virus was provided for any of the cases; diagnoses were based solely on clinical presentation. The cases consisted mostly of rashes; there were no reported TEAEs suggesting disseminated herpes zoster or other complications such as ophthalmic zoster or pneumonia.

Incidence of events reported under the preferred term of herpes simplex, another herpes virus that resides latent in peripheral neurons that can periodically reactivate when triggered by a variety of stimuli, was 9 participants (< 0.1%) in the mRNA-1273 group vs. 5 participants (< 0.1%) in the placebo group in 28 days of follow-up (Table 14.3.1.8.1.1) and 12 (< 0.1%) vs.

5 (< 0.1%), respectively in Part A (Table 14.3.1.8.1.3). One case resulted in the discontinuation of study treatment; a narrative for this subject is provided in Section 15.

Among participants in the mRNA-1273 group, underlying disorders considered associated with an increased risk of herpes zoster reactivation were reported in 5 participants (rheumatoid arthritis, psoriasis [receiving corticosteroids], type 1 diabetes mellitus [2 participants] (Papagianni et al 2018), and cancer [pelvic/colorectal]). One participant had herpes zoster at study entry and 2 participants had a documented previous history of herpes zoster. History of previous vaccination against herpes zoster was not systematically collected.

The incidence of herpes zoster in the US is estimated to range from 2.5 to 7.5 cases per 1000 person-years (Harpaz and Leung 2018). There is substantial variation by age, and incidence is higher in older adults. Compared with incidence of herpes zoster in individuals 50 years of age and older observed in a US population-based study (8.46 per 1000 person-years; Johnson et al 2015), the observed incidence of herpes zoster during Part A in the mRNA-1273 group (9.28 per 1000 person-years; rate ratio 1.10 [95% CI: 0.69, 1.74]) was within the expected incidence rate for the general population, while the observed incidence in the placebo group (3.45 per 1000 person-years; rate ratio 0.41 [95% CI: 0.22, 0.76]) was below the expected incidence rate (Table 7-14).

Table 7-14: Herpes Zoster Incidence per 1000 Person-Years in Part A Compared with US Expected Incidence

Treatment; Age	N	Person-years[a]	Observed		Expected[c]		Rate Ratio[d] (95% CI)[e]
			Cases	Rate[b]	Cases	Rate	
mRNA-1273	15,184	7592	50	6.59	33.9	4.47	1.47 (0.95, 2.28)
≤ 50 years	6991	3496	12	3.43	9.2	2.62	1.31 (0.55, 3.10)
> 50 years	8193	4097	38	9.28	34.7	8.46	1.10 (0.69, 1.74)
Placebo	15,162	7581	23	3.03	33.9	4.47	0.68 (0.40, 1.15)
≤ 50 years	7054	3527	9	2.55	9.2	2.62	0.97 (0.39, 2.44)
> 50 years	8108	4054	14	3.45	34.3	8.46	0.41 (0.22, 0.76)

Abbreviation: CI = confidence interval.

[a] Person-years were estimated based on the assumption of 6 months (or 0.5 years) of follow-up per participant and were calculated as (number of participants) × 0.5.

[b] The observed rate per 1000 person-years was calculated as (number of cases) / person-years × 1000.

[c] Johnson et al 2015.

[d] Incidence rate ratios were calculated as observed rate / expected rate.

[e] The 95% CIs were calculated as $_e\{\log(IRR)\pm[1.96\text{xSE}(\log(IRR))]\}$.

While the overall number of herpes zoster cases is higher in the mRNA-1273 group than the placebo group, the preponderance of herpes zoster cases reported in the mRNA-1273 group occurred more than 28 days after any dose, while in the placebo group the preponderance of events occurred within 28 days. This distribution does not support relatedness to mRNA-1273. In

addition, the observed incidence of herpes zoster in the mRNA-1273 group was within the expected incidence rate in the general population.

Other Events

- Lymphadenopathy was reported for 264 participants (1.7%) in the mRNA-1273 group and 127 participants (0.8%) in the placebo group; injection site lymphadenopathy was reported for 66 (0.4%) and 15 (< 0.1%) participants, respectively (Table 14.3.1.8.1.1); a few participants also had events that were coded as infusion site or vaccination site lymphadenopathy). Most of these events were localized/regional (ie, specified as axillary, cervical, or supraclavicular in verbatim terms) and ipsilateral to the injection site, as anticipated given the mechanism of action for this vaccine. Most events resolved within 14 days after onset. The reported characteristics of most events did not suggest generalized lymphadenopathy (ie, involving lymph nodes from multiple, distant regions). One event was reported as severe for a participant in the mRNA-1273 group; the event was described as left axillary ipsilateral lymphadenopathy, occurred 3 days after the second dose, was considered related to treatment, and resolved in 4 days. In the mRNA-1273 group, 29 participants had moderate lymphadenopathy (compared with 15 in the placebo group), and all other events were mild. Two participants in the mRNA-1273 group discontinued from vaccination in response to lymphadenopathy (Table 14.3.1.15.1): for 1 participant, the event was described as mild ipsilateral axillary lymphadenopathy, was considered related to treatment, began 5 days after dose 1, and resolved in 9 days; for another participant, the event was described as left armpit swelling, was considered related to treatment, began 4 days after dose 1, and resolved in 16 days (Listing 16.2.7.11).

- In the 28-day period, cervical radiculopathy was reported for 8 participants (< 0.1%) in the mRNA-1273 group and 1 participant (< 0.1%) in the placebo group (Table 7-15). Potentially relevant medical history was reported for 4 of the mRNA-1273 participants and included cervical radiculopathy, cervical spinal stenosis, and intervertebral disc degeneration for one participant for whom the event was reported as an SAE (moderate) and resolved in 2 days after anterior cervical discectomy and fusion; intervertebral disc compression, cervical radiculopathy, spinal stenosis, and osteoarthritis (neck and shoulders) for one participant; cervical radiculopathy for one participant; and intervertebral disc protrusion (C4-C7) for one participant. All events were mild to moderate in severity. One event was considered by the investigator to be related to study vaccine: the participant was a 70-year-old female, and mild cervical radiculopathy began and resolved on Day 2 after the second injection of mRNA-1273; the event was described as intermittent nerve pain in the neck and coincided with a moderate urinary tract

infection (which was considered not related to vaccination); the participant's medical history included osteopenia and parathyroidectomy. Seven of the participants were using concomitant pain medications. The side of the cervical radiculopathy was documented in one participant in the mRNA-1273 group; the participant had neck pain, shoulder pain, and radiculopathy contralateral to the injection site. In Part A, cervical radiculopathy was reported for 17 participants (0.1%) in the mRNA-1273 group and 2 participants (< 0.1%) in the placebo group (Table 14.3.1.8.1.3).

- In the 28-day period, facial bones fracture was reported for 4 participants in the mRNA-1273 group (1 event was an SAE in an 80-year-old participant) and no participants in the placebo group (Table 14.3.1.8.1.1). Over the duration of Part A, facial bones fracture was reported for 8 participants in the mRNA-1273 group and 1 participant in the placebo group (Table 14.3.1.8.1.3). In the mRNA-1273 group, the onset day of the event relative to the start of the study ranged from Day 14 to Day 144. All events resolved and were considered not related to study vaccine by the investigator. At least one fracture of any kind was reported for 122 participants (0.8%) in the mRNA-1273 group and 121 participants (0.8%) in the placebo group. In addition, no imbalance was observed for fall events (21 participants [0.1%] in the mRNA-1273 group and 27 participants [0.2%] in the placebo group within 28 days and 46 vs. 48 participants, respectively [0.3% in each group] during Part A) (Table 14.3.1.8.1.1 and Table 14.3.1.8.1.3).
- Vertigo or positional vertigo was reported during the 28-day follow-up for 30 (0.2%) vs. 19 (0.1%) participants in the mRNA-1273 and placebo groups, respectively. All events were nonserious and resolved (or were resolving). Vertigo was severe for one participant in the mRNA-1273 group (and occurred on the day of the second dose [at night after the injection] and resolved the following day) and severe for 3 participants in the placebo group (occurred on Day 11, 21, and 25 after the first injection). Four events in each group were assessed by the investigator to be treatment-related (Table 14.3.1.11.1.1). In the mRNA-1273 group, relative to the most recent dose, onset of vertigo events was on the day of the dose for 1 event, on Day 1 after the dose for 2 events, and on Day 3, 6, and 7 after the dose for 1 event each. Also in the mRNA-1273 group, positional vertigo occurred 3 days after the first dose for a participant with a history of positional vertigo and 4 days after the first dose for a participant who was 71 years old and had dyskinesias and was taking a semaglutide; all other events occurred between 11 and 23 days after the first or second dose. All positional vertigo events were mild to moderate in severity, nonserious, and resolved with exception of an event that was associated with Meniere's disease. During Part A, vertigo or positional vertigo was reported for 54 participants (0.4%) in the mRNA-1273 group and for 40 participants (0.3%) in the placebo group. No

imbalance was observed between the groups in the SMQ analysis for hearing and vestibular disorders (Section 7.3.3.3).

- In the 28-day period, facial paralysis was reported for 2 participants in the mRNA-1273 group (verbatim terms of Bell's palsy and left side face paralysis) and 1 participant in the placebo group (verbatim term of Bell's palsy). During Part A, facial paralysis was reported for 8 participants in the mRNA-1273 group and 3 participants in the placebo group. One event of facial paralysis (Bell's palsy) was reported as an SAE for a participant treated with mRNA-1273 (Section 7.3.2). One event in the mRNA-1273 group was reported as left facial palsy; the participant had mild viral infection at the time. All other events in both groups were reported as Bell's palsy. One participant with Bell's palsy had underlying worsening of migraine that was treated with injections of botulinum toxin. Within the mRNA-1273 group, a concomitant AE of infection was reported for 4 of the 6 Bell's palsy events. One mild event in the mRNA-1273 group was considered related to treatment. Three Bell's palsy events were reported as severe (all in the mRNA-1273 group). No notable imbalance was observed in the SMQ analysis for demyelination (Section 7.3.3.3).
- In the 28-day period, events of paresthesia, hyperesthesia, hypoesthesia, injection site paresthesia, injection site hypoesthesia, and dysesthesia were reported in the mRNA-1273 and placebo groups, respectively, as follows: paresthesia 34 (0.2%) vs. 27 (0.2%); hyperesthesia 6 (< 0.1%) vs. 0; hypoesthesia 13 (< 0.1%) vs. 9 (< 0.1%); injection site paresthesia 6 (< 0.1%) vs. 3 (< 0.1%); injection site hypoesthesia 3 (< 0.1%) vs. 1 (< 0.1%); and dysesthesia 0 vs. 3 (< 0.1%) (Table 14.3.1.8.1.1). One participant in the placebo group experienced 2 SAEs of paresthesia beginning 7 days after the first dose that were considered moderate, assessed as related to treatment, and resolved. One participant in the mRNA-1273 group who experienced paresthesia did not receive the second dose although the action taken with study vaccine was reported as "dose not changed;" 3 participants in the placebo group who experienced paresthesia did not receive the second dose; the event in the mRNA-1273 group was described as moderate "tingling in hands" that began on Day 3 after the first dose and resolved on Day 34 and was not considered related to treatment. A severe event of injection site hypoesthesia was reported for 1 participant in the mRNA-1273 group with onset on Day 3 after the first dose that was considered related to treatment and resolved on Day 5. Two severe events of paresthesia were reported for 1 participant in the placebo group with onset on Day 163 after the first dose that were not considered related to treatment (one event resolved and the other was ongoing).

Table 7-15: Participant Incidence of Unsolicited Treatment-Emergent Adverse Events (at Least 1% in Any Treatment Group or Rate Ratio 95% Confidence Interval Does Not Include 1, Based on Preferred Term) by System Organ Class and Preferred Term up to 28 Days After Any Injection (Safety Set)

System Organ Class Preferred Term	Placebo (N=15162) n (%)	mRNA-1273 (N=15184) n (%)	Rate Ratio (95% CI)	Total (N=30346) n (%)

A treatment-emergent adverse event (TEAE) is defined as any event not present before exposure to study vaccination or any event already present that worsens in intensity or frequency after exposure.

Percentages are based on the number of safety subjects. The rate ratio is calculated as the ratio of percentage of participants reporting the event in mRNA-1273 divided by that in Placebo; rate ratio is provided for TEAEs with at least 7 subjects in any vaccination group reporting the event. The 95% CI is calculated using the Miettinen and Nurminen method.

MedDRA version 23.0.

Source: Table 14.3.1.8.1.1.

7.2.3 Unsolicited Adverse Events by Maximum Intensity

The incidence of severe TEAEs was similar between the mRNA-1273 and placebo treatment groups in the 28-day follow-up period (1.7% and 1.5%, respectively; Table 14.3.1.18.1.1). Hypertension was reported as severe for 28 and 34 participants, in the mRNA-1273 and placebo treatment groups, respectively (0.2% in each group); no other event was reported as severe for > 0.1% of participants in either group. Events that were reported as severe for more participants in the mRNA-1273 group than in the placebo group, respectively, were fatigue (20 vs. 9), headache (14 vs. 11), myalgia (9 vs. 4), and blood pressure increased (10 vs. 6). All except the last were among the solicited systemic ARs, which were reported as TEAEs if they persisted beyond Day 7 after any injection (in which case they are counted both with solicited ARs and with unsolicited TEAEs) or started on Day 8 or later after any injection.

The incidence of severe TEAEs assessed by the investigator as related to investigational product was higher in the mRNA-1273 group compared with the placebo group in the 28-day follow-up period (0.5% and 0.2%, respectively; Table 14.3.1.18.1.1). Events that were reported as severe and assessed by the investigator to be treatment-related for more participants in the mRNA-1273 group than in the placebo group, respectively, were fatigue (16 vs. 6) and myalgia (8 vs. 2), both of which were among the solicited systemic ARs.

7.2.4 Unsolicited Adverse Events by Relationship to Investigational Product

More participants in the mRNA-1273 group (13.6%) than in the placebo group (8.2%) had unsolicited TEAEs during the 28-day follow-up that were assessed by the investigator as related to investigational product (Table 7-16). Most of the imbalance is in events that were also solicited ARs (injection site events, headache, nausea, vomiting, pyrexia, chills) or similar to ARs (lymphadenopathy, neck pain, back pain, and musculoskeletal pain). Imbalances were also observed for less common events including diarrhea (44 vs. 32), nasal congestion (21 vs. 9), dizziness (28 vs. 13), urticaria (22 vs. 7), paresthesia (14 vs. 9), rhinorrhea (13 vs. 8), cough (13 vs. 5), rash (11 vs. 3), erythema (9 vs. 0), and insomnia (7 vs. 1).

Table 7-16: Participant Incidence of Unsolicited Treatment-Emergent Adverse Events Assessed by the Investigator as Treatment-Related by System Organ Class and Preferred Term up to 28 Days After Any Injection (Safety Set)

System Organ Class Preferred Term	Placebo (N=15162) n (%)	mRNA-1273 (N=15184) n (%)	Rate Ratio (95% CI)	Total (N=30346) n (%)

A treatment-emergent adverse event (TEAE) is defined as any event not present before exposure to study vaccination or any event already present that worsens in intensity or frequency after exposure.

Percentages are based on the number of safety subjects. The rate ratio is calculated as the ratio of percentage of participants reporting the event in mRNA-1273 divided by that in Placebo; rate ratio is provided for TEAEs with at least 7 subjects in any vaccination group reporting the event. The 95% CI is calculated using the Miettinen and Nurminen method.

MedDRA version 23.0.

Source: Table 14.3.1.11.1.1.

7.2.5 Unsolicited Adverse Events Occurring Within 30 Minutes After Injection

Participants were to remain in the clinic for 15 minutes (or 30 minutes if they had a history of allergies) after each injection for observation because of concerns about potential anaphylaxis. No anaphylaxis was reported within 30 minutes after any injection (Table 14.3.1.19.6.3). The incidence of TEAEs, severe TEAEs, and MAAEs occurring within 30 minutes after any injection, regardless of relationship to the IP was similar in participants who received mRNA-1273 (0.8%) and those who received placebo (0.7%) (Table 7-17). Few of the events were MAAEs and/or severe, none were considered SAEs, and none led to discontinuation from the study or study vaccine in the mRNA-1273 group.

At least one unsolicited TEAE that occurred within 30 minutes after the first injection was reported for 74 participants (0.5%) and 68 participants (0.4%) in the mRNA-1273 and placebo groups, respectively (Table 14.3.1.19.5.1). Fewer participants experienced such events after the second injection (47 [0.3%] vs. 41 [0.3%] [Table 14.3.1.19.5.2]). All reported event terms were consistent with expected physiological reactions to injections. No imbalances between the groups were apparent, and no single participant had a severe TEAE within 30 minutes after both injections. Only 2 events in the placebo group led to discontinuation from study vaccine; no such events were reported in the mRNA-1273 group.

Table 7-17: Summary of Immediate Unsolicited Adverse Event Occurring Within 30 Minutes of Any Vaccination (Safety Set)

	Placebo (N=15162) n (%)	mRNA-1273 (N=15184) n (%)	Total (N=30346) n (%)
Unsolicited TEAEs regardless of relationship to study vaccination			
All	105 (0.7)	118 (0.8)	223 (0.7)

Leading to discontinuation from study vaccine	0	0	0
Leading to discontinuation from participation in the study	0	0	0
Severe	1 (<0.1)	2 (<0.1)	3 (<0.1)

A treatment-emergent adverse event (TEAE) is defined as any event not present before exposure to study vaccination or any event already present that worsens in intensity or frequency after exposure.

N = Number of participants in Safety Set who received any injection

n = Number of participants who reported AEs in specified category

Source: Table 14.3.1.19.5.3.

7.2.6 Subgroup Analyses of Unsolicited Adverse Events

7.2.6.1 Age Groups

The incidence of unsolicited TEAEs was similar in both the younger (≥ 18 to < 65 years; 29.7% of 22,826 participants) and older (≥ 65 years; 30.6% of 7520 participants) age groups; this was also true for TEAEs assessed as treatment-related by the investigator (Table 14.3.1.7.2.1.1). Further, no apparent differences in the incidence of unsolicited TEAEs were observed across the

older age subgroups: 30.5% of 6122 participants aged ≥ 65 to < 75 years, 30.9% of 1308 participants aged ≥ 75 to < 85 years, and 34.4% of 90 participants aged ≥ 85 years) (Table 7-18).

In the older age group, reported incidence was numerically higher than in the younger age group in the following SOCs: musculoskeletal and connective tissue disorders (567/7520 [7.5%] vs. 592/22826 [6.4%]); vascular disorders (144/7520 [1.9%] vs. 258/22826 [1.1%]); metabolism and nutrition disorders (77/7520 [1.0%] vs. 164/22826 [0.7%]); cardiac disorders (66/7520 [0.9%] vs. 88/22826 [0.4%]); benign, malignant, and unspecified neoplasms (including cysts and polyps) (63/7520 [0.8%] vs. 55/22826 [0.2%]); eye disorders (53/7520 [0.7%] vs. 84/22826 [0.4%]); ear and labyrinth disorders (49/7520 [0.7%] vs. 115/22826 [0.5%]); and renal and urinary disorders (45/7520 [0.6%] vs. 51/22826 [0.2%]) (Table 14.3.1.8.2.1.1). These types of events are generally consistent with expected increased frequency of TEAEs in an older population.

The most common unsolicited TEAEs by age group (≥ 2% of participants overall) were as follows:

- ≥ 18 to < 65 years (N = 22826): headache (5.1%), fatigue (4.7%), myalgia (2.6%), and arthralgia (2.4%) (Table 14.3.1.8.2.1.1).
- ≥ 65 to < 75 years (N = 6122): fatigue (4.4%), headache (3.5%), arthralgia (2.9%), and myalgia (2.4%) (Table 14.3.1.8.2.2.1).
- ≥ 75 to < 85 years (N = 1308): fatigue (4.7%), arthralgia (3.6%), headache (3.3%), and myalgia (2.7%) (Table 14.3.1.8.2.2.1).
- ≥ 85 years (N = 90): arthralgia (4.4%); myalgia and diarrhea (3.3% each); and urinary tract infection, hypertension, gastroesophageal reflux disease, and injection site pain (2.2% each) (Table 14.3.1.8.2.2.1).

The overall incidence of severe unsolicited TEAEs was higher in the older age group (2.2%) compared with the younger age group (1.4%) (Table 14.3.1.17.1.2). No difference was apparent between the age groups in the overall incidence of severe unsolicited TEAEs assessed by the investigator to be treatment-related (Table 14.3.1.18.1.2).

Analysis of unsolicited TEAEs by age group did not reveal any new clinically relevant imbalances between the mRNA-1273 and placebo groups compared with the overall population.

Table 7-18: Summary of Unsolicited Treatment-Emergent Adverse Events by Age Groups (< 65, ≥ 65 and < 75, ≥ 75 and < 85, and ≥85) up to 28 Days After Any Injection (Safety Set)

A treatment-emergent adverse event (TEAE) is defined as any event not present before exposure to study vaccination or any event already present that worsens in intensity or frequency after exposure.

Percentages are based on the number of safety subjects.

Source: Table 14.3.1.7.2.2.1.

7.2.6.2 Baseline SARS-CoV-2 Status

Baseline SARS-CoV-2 status was negative for most participants. Incidence of unsolicited TEAEs within 28 days after any injection among participants with negative baseline status reflect that of the overall population. In the Safety Set, 347 participants in the mRNA-1273 group and 337 participants in the placebo group had positive baseline SARS-CoV-2 status (Table 14.1.3.2.2). Among these participants, incidence of TEAEs was numerically lower in the mRNA-1273 group (22.2%) than in the placebo group (27.3%) (Table 14.3.1.7.3.1) and

compared with incidence in the overall mRNA-1273 population (31.3%) (Table 14.3.1.7.1.1). Incidence was similarly lower in the mRNA-1273 group for severe TEAEs, SAEs, MAAEs, and TEAEs considered related to treatment. The comparison is limited by the small number of baseline positive participants.

The most common TEAEs within 28 days after any injection were similar between participants with either a positive or negative baseline SARS-CoV-2 status (Table 14.3.1.8.3.1).

A treatment-emergent adverse event (TEAE) is defined as any event not present before exposure to study vaccination or any event already present that worsens in intensity or frequency after exposure.

Percentages are based on the number of safety subjects.

Source: Table 14.3.1.7.3.1.

7.2.6.3 Race and Ethnicity

The incidence of unsolicited TEAEs was similar across the race groups (Table 14.3.1.7.4.1) and ethnic groups (Table 14.3.1.7.5.1).

7.2.6.4 Sex

The observed incidence of unsolicited TEAEs during the 28-day follow-up was higher in females (35.5% of 7266 participants in the mRNA-1273 group) and lower in males (27.4% of 7918 participants in the mRNA-1273 group) (Table 14.3.1.7.7.1). The difference between the mRNA-1273 and placebo groups, respectively, was larger for females (35.5% vs. 31.6%) than for males (27.4% vs. 26.0%). The reported TEAEs were similar for both sexes and the most common TEAEs were headache, fatigue, headache, myalgia, and arthralgia (Table 14.3.1.8.7.1).

7.2.6.5 Risk Factor for Severe COVID-19

The incidence of unsolicited TEAEs in the mRNA-1273 group was 34.5% in the At Risk subgroup (3448 participants) and 30.4% in the Not At Risk subgroup (11,736 participants) (Table 14.3.1.7.6.2.1). As expected based on their medical history, serious TEAEs were reported at a higher rate in the At Risk group (1.0% in the mRNA-1273 group) compared with the Not At Risk group (0.5% in the mRNA-1273 group). There was little difference within risk subgroups

between the mRNA-1273 and placebo groups. The overall incidence of unsolicited TEAEs for the individual risk groups was similar (Table 14.3.1.7.6.3.1).

Among participants with HIV, the incidence of unsolicited TEAEs up to 28 days after any IP administration was generally similar between the mRNA-1273 group (35/94 [37.2%]) and the placebo group (38/91 [41.8%]; Table 14.3.1.7.8.1). The incidence of unsolicited TEAEs that were assessed as treatment-related was also similar between the mRNA-1273 (11/94 [11.7%]) and placebo (10/91 [11.0%]) groups.

7.2.6.6 Participants With Autoimmune Disorders

Among the 2296 participants with an autoimmune disorder reported at baseline, the incidence of unsolicited TEAEs up to 28 days after any injection was 35.0% compared with 30.0% in the overall population. However, even in this large population of participants with at least one autoimmune disorder at baseline, no difference in TEAE incidence was observed between the mRNA-1273 group (36.7% of 1152 participants) and the placebo group (33.2% of 1144 participants) (Table 14.3.1.7.9.1). Events that were assessed as treatment-related were more commonly reported by participants who received mRNA-1273 (16.8%) than by those who received placebo (9.3%), as was observed in the overall study population. This is consistent with the observed higher incidence in the mRNA-1273 group of TEAEs that were associated with reactogenicity (ARs or similar to ARs), including fatigue, injection site conditions, and arthralgia (Table 14.3.1.8.9.1). No cases of autoimmune disease exacerbations were explicitly reported.

7.3 Deaths, Other Serious Adverse Events, and Other Significant Unsolicited Adverse Events

7.3.1 Deaths

A total of 32 deaths were reported in Part A, including 16 participants (0.1%) in each group (Table 7-20); the table does not reflect 1 additional participant in the mRNA-1273 group who died during Part B due to a TEAE that began during Part A (Section 7.2.1.2). No trends were apparent in the timing or causes of deaths (Table 7-22). Baseline age was ≥ 65 years for 9 of the participants in the mRNA-1273 group and 6 participants in the placebo group (Listing 16.2.7.14). None of the unsolicited TEAEs leading to death were considered to be related to the IP.

COVID-19 was reported as the event leading to death for 1 participant in the mRNA-1273 group and 3 participants in the placebo group. The participant in the mRNA-1273 group was 74 years old and received dose 1 but not dose 2. No TEAEs were reported as leading to discontinuation of vaccine, but the participant is noted as having “refused second injection due to side effects

however, consented to continue study visits" (Listing 16.2.1.1). Reported TEAEs within 8 days of Day 1 were severe nausea and severe fatigue that were considered related to treatment. On Study Day 120, 119 days after the first dose, the participant began to experience symptoms of COVID-19. On Study Day 127, the participant tested positive for SARS-CoV-2 via RT-PCR. The event of COVID-19 lasted for 56 days and the participant died on Study Day 175. This participant was not included in the PP Set due to receipt of an incomplete vaccination regimen.

A listing of the deaths is presented in Listing 16.2.12 and a listing of unsolicited AEs leading to death is presented in Listing 16.2.7.14.

Case narratives for the participants who experienced a fatal TEAE are provided in Section 15.

Table 7-20: Summary of Death in Part A (Safety Set)

	Placebo (N=15162)	mRNA-1273 (N=15184)	Total (N=30346)
Number of deaths, n (%)	16 (0.1)	16 (0.1)	32 (0.1)
From randomization up to 14 days after first injection	2	0	2
>=14 up to 21 days after first injection	0	2	2
>=21 days after first injection up to second injection	1	2	3
From second injection up to 7 days after second injection	0	0	0
>=7 up to 14 days after second injection	0	0	0
>=14 up to 28 days after second injection	0	0	0
>=28 up to 56 days after second injection	2	2	4
>=56 up to 84 days after second injection	2	4	6
>=84 up to 112 days after second injection	6	3	9
>=112 days after second injection	3	3	6

Percentages are based on the number of subjects in Safety Set.

Abbreviations: IP = investigational product.

[a] Relationship is based on investigator assessment.

[b] This participant is not counted in Table 7-20 because the event began during Part A but the fatal outcome occurred during Part B (Section 7.2.1.2).

Source: Listing 16.2.7.14.

7.3.2 Other Serious Adverse Events

No difference was observed between the groups in the rates of reported SAEs during Part A (1.8% in the mRNA-1273 group [401 events] and 1.9% in the placebo group [439 events]) (Table 7-22). COVID-19 was reported as a serious TEAE for 2 (< 0.1%) participants in the mRNA-1273 group and for 40 (0.3%) participants in the placebo group. No other event was reported as an SAE in ≥ 0.1% of participants in either group. At least 1 SAE that was considered related to treatment was reported for 12 participants (< 0.1%) in the mRNA-1273 group and 4 participants (< 0.1%) in the placebo group (Table 7-23). Swelling of the face was reported as a treatment-related SAE for 2 participants in the mRNA-1273 group and 1 participant in the placebo group (further information below); no other event was reported as treatment-related for more than 1 participant in either group or overall. The other SAEs that were reported as treatment-related during Part A were B-cell small lymphocytic lymphoma, Basedow's disease, autonomic nervous system imbalance, cerebrovascular accident, multiple sclerosis, swelling of the face, nausea and vomiting, alopecia areata, angioedema, rheumatoid arthritis, and pericardial effusion and pericarditis and pleural effusion (described further below) in the mRNA-1273 group and polymyalgia rheumatica; acute myocardial infarction, hypomagnesemia, acute kidney injury, and atrial fibrillation, organizing pneumonia, and respiratory failure (single participant); swelling of the face, immunization anxiety related reaction, feeling hot, and paresthesia (single participant); and procedural hemorrhage in the placebo group. The incidence of SAEs within the 28-day follow-up period was lower in both groups than in Part A and similarly balanced (0.6% in the mRNA-1273 group [140 events] and 0.7% in the placebo group [147 events]) (Table 14.3.1.13.1.1).

Detailed information about all SAEs is available in Section 15. Notable events are briefly described here.

Dyspnea

Dyspnea was reported as an SAE for 5 participants in the mRNA-1273 group and 0 participants in the placebo group. The events were not considered related to treatment. All participants were ≥ 52 years of age at study entry and their baseline BMI was ≥ 30.0 kg/m^2. None of the events were consistent with possible myocarditis or pericarditis; the events occurred 13 days after dose 1 and 35, 81, 88, and 137 days after dose 2; and 4 of the 5 participants had pre-existing cardiac disease. Details are as follows:

- 52-year-old male: Grade 4 dyspnea had onset on Day 81 after the second dose and resolved on Day 93. It coincided with Grade 4 upper respiratory tract infection and severe abdominal pain. The participant's medical history included non-ST myocardial infarction,

cardiomyopathy, systolic congestive heart failure, pulmonary hypertension, obesity, and mitral regurgitation. The event was treated with antibiotics and resolved.

- 62-year-old female: Severe dyspnea had onset on Day 35 after the second dose and resolved on Day 50. It coincided with severe tachycardia; other events ongoing at time of onset were abdominal discomfort, discolored feces, headache, otitis media, and fatigue. The participant's medical history included heart murmur. The dyspnea was associated with possible lung infiltrates and resolved with antibiotics.
- 62-year-old male: Grade 4 dyspnea had onset on Day 13 after the first dose and resolved on Day 66. It coincided with severe paroxysmal atrial flutter and Grade 4 myocardial infarction, heart failure, acute coronary syndrome, and atrial fibrillation with rapid ventricular response. Study vaccine was discontinued in response to the myocardial infarction. The dyspnea resolved on Day 66 and was considered a sequela of the myocardial infarction. The participant's medical history included hypertension, heart murmur, irregular heart rhythm, closure of atrial septal defect, and coronary artery disease with calcified lesion.
- 62-year-old male: Grade 4 dyspnea had onset on Day 137 after the second dose and resolved on Day 140. It coincided with Grade 4 dysphasia. The participant's medical history included right ventricle dysplasia, asthma, and cardiac stents. The event was associated with a post-operative seroma after cervical discectomy.
- 64-year-old female: Severe dyspnea had onset on Day 88 after the second dose and resolved on Day 90. It was associated with fluid in the lungs and resolved with furosemide. The participant's medical history included HIV and a cancerous inguinal tumor.

Pericarditis

Pericarditis was reported as an SAE for 2 participants in the mRNA-1273 group (1 each male and female described below) and 2 in the placebo group (1 each male and female; the male participant had 3 hospitalizations for a single medical event). Another participant in the placebo group had an SAE of pericardial effusion. No cases of concomitant myocarditis were reported. Information about pericarditis events among participants who received mRNA-1273 is as follows:

- 65-year-old male: Grade 4 pericarditis had onset on Day 73 after the second dose and resolved on Day 74. The participant did not have prior history of cardiac disease but had experienced an SAE of myocardial infarction on Days 54 to 57 after the second dose and had undergone cardiac catheterization and stent placement.

- 59-year-old female: Moderate pericarditis and Grade 4 pericardial effusion had onset on Day 68 after the second dose (pericardial effusion had started at moderate severity on the previous day). Grade 4 pleural effusion began on Day 69. All 3 events were considered related to study vaccine. All 3 events resolved on Day 166 after the second dose. The participant's medical history included enlarged descending aorta and thoracic aorta ectasia. The participant had visited an emergency department with shortness of breath and chest pain on Day 5 after the second dose (grade 4 chest pain and moderate fatigue were reported as TEAEs). In addition, the participant had experienced sinus infection and received an influenza vaccination approximately 1 month before the events.

Stroke and Thrombotic Events

Cerebrovascular accident, stroke, or transient ischemic attack were reported for 10 participants in the mRNA-1273 group and 7 participants in the placebo group. Event onset occurred within 28 days after the last dose for 3 participants in the mRNA-1273 group and 2 participants in the placebo group and more than 28 days after the last dose for 7 and 5 participants in the mRNA-1273 and placebo groups, respectively. One event of cerebrovascular accident was considered by the investigator to be related to study treatment (described below). No cases were associated with thrombocytopenia. The age and sex distribution of the participants with these SAEs was similar between the groups, and all participants in both groups had at least one relevant risk factor for the event; these included previous stroke, hypertension, hypercholesterolemia, type 2 diabetes, heart failure, and congenital heart disease. Further details of events in the mRNA-1273 group are as follows:

- 68-year-old female: Severe cerebrovascular accident (right occipital lobe) had onset on Day 4 after the first dose and resolved on Day 5. The participant's medical history included sinus bradycardia and hypertension.
- 77-year-old female: Moderate embolic stroke (left frontal lobe subcortical white matter) had onset on Day 48 after the second dose and resolved on the same day. The participant's medical history included hypertension and psoriatic arthritis.
- 72-year-old male: Severe cerebrovascular accident (left middle cerebral artery lacunar stroke) had onset on Day 118 after the second dose and resolved on the same day. The participant's medical history included hyperlipidemia.
- 56-year-old male: Grade 4 cerebrovascular accident (right occipital lobe) had onset on Day 34 after the second dose and resolved on the same day. The participant's medical history included type 2 diabetes, coronary artery bypass graft, cardiac edema, coronary artery disease, stent placement, hypertriglyceridemia, hypertension,

hypercholesterolemia, myocardial infarction, hyperlipidemia, chronic obstructive pulmonary disease, tobacco and alcohol abuse and dependency, and atrial fibrillation.

- 66-year-old male: Grade 4 cerebrovascular accident (location not reported) had onset on Day 26 after the second dose and resolved on Day 28. The participant's medical history included hypertension, hyperlipidemia, type 2 diabetes, vascular stent placement. The participant had also received an influenza vaccination.
- 60-year-old female: Grade 4 cerebrovascular accident (right frontoparietal infarct) had onset on Day 93 after the second dose and did not resolve. The participant's medical history included chronic obstructive pulmonary disease, hyperlipidemia, hypertension, type 2 diabetes, carotid artery disorder, previous transient ischemic attack, previous smoking, coronary artery disease, and obesity. The cerebrovascular accident occurred after cervical spine stenosis, nerve impingement, fall, and hematoma of the neck and resultant acute respiratory failure.
- 71-year-old female: Grade 4 embolic stroke (multiple left hemisphere embolic infarct) had onset on Day 9 after the second dose (together with staphylococcal pneumonia, cervical vertebral fracture, and traumatic liver injury, all grade 4) on the day after a grade 4 road traffic accident. The participant had grade 4 carotid artery thrombosis and grade 4 acute myocardial infarction on Day 13 after the second dose, and grade 4 craniocerebral injury and grade 4 subarachnoid hemorrhage were reported on Day 23 after the second dose. None of the events was considered to be related to treatment. The outcome of the stroke was not resolved and the outcome of the carotid artery thrombosis was unknown. The participant's medical history included hypertension.
- 45-year-old male: Grade 4 transient ischemic attack (location not reported) had onset on Day 15 after the second dose and resolved on Day 16. The participant's medical history included hyperlipidemia.
- 75-year-old male: Grade 4 transient ischemic attack (right paramedian pontine infarct) had onset on Day 86 after the second dose and resolved on Day 90. The participant's medical history included high cholesterol, high blood pressure, and obesity.
- 34-year-old female: Severe cerebrovascular accident had onset on Day 67 after the first dose and resolved on Day 82. The event was considered to be related to treatment. The participant's medical history included nonserious mild COVID-19 (the participant had only received 1 dose of vaccine). Imaging showed acute left posterior inferior cerebellar artery territory infarct mass effect on the fourth ventricle. The participant had a patent foramen ovale that was surgically repaired during this same hospital admission.

In addition, a 62-year-old female had an event with the reported term of cerebrovascular accident (moderate) that was not considered an SAE but was reported based on findings in a computed tomography scan (performed after a seizure) were suggestive of subacute to remote infarction. The onset of the event was reported as Day 12 and it was described as ongoing, but the participant withdrew consent for unrelated reasons, so no further information was available.

During Part A, there were no reports of idiopathic thrombocytopenic purpura or thrombosis with thrombocytopenia syndrome (the few cases of thrombocytopenia did not occur in connection with thrombosis events) and there were no reports of cerebral venous sinus thrombosis or dural venous thrombosis. An SAE of nonarteritic ischemic optic nerve neuritis (verbatim term; preferred term was optic neuritis) together with nonserious papilledema was reported in a 66-year-old female participant treated with mRNA-1273, but there was no evidence of cerebral vasculitis, aneurysm, stenosis, or abnormal vascularity.

Deep vein thrombosis was reported as an SAE for 4 and 1 participant(s) in the mRNA-1273 and placebo groups, respectively. The event was reported as a TEAE (regardless of seriousness) for 8 and 6 participants, and no imbalance was observed in the SMQ for embolic and thrombotic events (Table 14.3.1.22.12). Among the SAEs, all events were reported in participants 55 years of age or older, occurred at least 41 days after the most recent vaccination, none were considered related to treatment, and all resolved. Among participants in the mRNA-1273 group, details are as follows: one participant had medical history including varicose veins and peroneal nerve paralysis and the deep vein thrombosis was noted incidentally during scheduled colonoscopy; one participant had medical history including hyperlipidemia and had recently had increased sedentary lifestyle; one participant had medical history including alpha thalassemia and the deep vein thrombosis occurred after the participant developed an abscess after a planned surgical procedure; and one participant had medical history including thrombophilia, thrombus, obesity, and multiple pulmonary embolisms.

A numerical imbalance was observed in the CNS vascular disorders SMQ (Section 7.3.3.3.5) due to the inclusion of subarachnoid hemorrhage and subdural hematoma that were of traumatic etiology. In the mRNA-1273 group, subarachnoid hemorrhage was reported as an SAE in 3 participants in the mRNA-1273 group and subdural hematoma was reported as an SAE in 2 participants; neither event was reported in the placebo group. None of the events were considered related to treatment and all were due to accidents. Subarachnoid hemorrhage was reported after a motor vehicle accident 7 days after the second dose for a 71-year-old female (investigator noted, “did not experience a medical condition that caused the motor vehicle accident”); after a fall in ice and snow 83 days after the second dose for a 73-year-old male; and after a fall after an episode of severe syncope (not considered related to treatment) 16 days after the second dose for a 57-year-old female whose medical history included iron deficiency anemia,

benign brain tumor excision, blurry vision, and headaches; brain imaging during hospitalization showed a Chiari malformation that was considered congenital). Subdural hematoma was reported after a head and neck injury from a fall for an 80-year-old participant and for a 65-year-old participant. One 59-year-old participant had both subarachnoid hemorrhage and subdural hematoma that were not reported as SAEs but were also due to a head injury from a fall.

Facial Swelling

An SAE of swelling face was reported as related to treatment for 2 participants in the mRNA-1273 group and 1 participant in the placebo group. None of the events required hospitalization. For a 51-year-old female, the event occurred on Day 3 after her second dose of mRNA-1273 and resolved on Day 8. The participant had received cosmetic injections including dermal fillers in both cheeks approximately 2 weeks before the second dose. For a 46-year-old female, the event was described as bilateral cheek swelling, occurred on Day 1 after the second dose of mRNA-1273, and resolved on Day 7. The participant had received dermal fillers approximately 5 and 6 months before the first and second injections, respectively. For a 41-year-old female, the event was described as swelling to the right side of the face, occurred on Day 7 after the first dose of placebo, and resolved on Day 17. The placebo participant had no reported history of dermal filler use; the event appeared to be associated with prior dental work. None of the other TEAEs within the CMQ for dermal filler reaction post vaccination were reported as SAEs, and incidence of the events did not appear to be imbalanced between the groups (Section 7.3.3.3.4).

Swelling of the face was reported as a nonserious TEAE for 3 participants in each group in the 28-day follow-up period (Table 14.3.1.8.1.1) and for 6 participants in the mRNA-1273 group and 4 participants in the placebo group in Part A (Table 14.3.1.8.1.3).

Facial Paralysis

One participant in the mRNA-1273 group had an SAE of facial paralysis that was not considered to be related to the study vaccine. The event occurred in a 67-year-old female participant, was described as Bell's palsy, occurred on Day 32 after the second dose, and resolved after approximately 7 weeks. The participant's medical history included cerebrovascular accident, hypertension, and type 2 diabetes mellitus. The participant had received an influenza vaccine approximately 2 weeks before the event. Nonserious TEAEs of facial paralysis and/or Bell's palsy are described in Section 7.2.2.

Other Events

- Seizure was reported as an SAE for 3 participants in the mRNA-1273 group and 1 participant in the placebo group. None of the events were considered related to treatment. No imbalance was evident in analyses using the SMQ for convulsions (Section 7.3.3.3).

- Nephrolithiasis was reported as an SAE for 5 participants in the mRNA-1273 group and 1 participant in the placebo group. None of the events were considered related to treatment. Among the 5 participants in the mRNA-1273 group, 4 had a history of nephrolithiasis.
- Although some autoimmune disorders were reported as SAEs in both groups, no cases of autoimmune disease exacerbations were explicitly reported, and no imbalance was evident in analyses using the CMQ for autoimmune disorders (Table 14.3.1.22.9).

Table 7-22: Participant Incidence of Serious Treatment-Emergent Adverse Events by System Organ Class and Preferred Term in Part A (Safety Set)

System Organ Class Preferred Term	Placebo (N=15162) n (%)	mRNA-1273 (N=15184) n (%)	Rate Ratio (95% CI)	Total (N=30346) n (%)
Number of subjects reporting unsolicited adverse events	292 (1.9)	268 (1.8)		560 (1.8)
Number of unsolicited adverse events	439	401		840
Infections and infestations	77 (0.5)	48 (0.3)		125 (0.4)
Pneumonia	11 (<0.1)	9 (<0.1)	0.82 (0.35, 1.92)	20 (<0.1)
Appendicitis	5 (<0.1)	4 (<0.1)		9 (<0.1)
Sepsis	3 (<0.1)	4 (<0.1)		7 (<0.1)

A treatment-emergent adverse event (TEAE) is defined as any event not present before exposure to study vaccination or any event already present that worsens in intensity or frequency after exposure.

Percentages are based on the number of safety subjects. The rate ratio is calculated as the ratio of percentage of participants reporting the event in mRNA-1273 divided by that in Placebo; rate ratio is provided for TEAEs with at least 7 subjects in any vaccination group reporting the event. The 95% CI is calculated using the Miettinen and Nurminen method.

7.3.3 Other Clinically Meaningful Unsolicited Adverse Events

7.3.3.1 Unsolicited Adverse Events Leading to Discontinuation From the Study Vaccine or From the Study

The participant incidence of unsolicited TEAEs leading to discontinuation from the study vaccine in Part A was lower in the mRNA-1273 group (0.5%; 87 events) than in the placebo group (0.7%; 123 events) (Table 7-24). The most frequently reported TEAE leading to discontinuation from the study vaccine was COVID-19 (14 participants [< 0.1%] in the mRNA-1273 group vs. 53 participants [0.3%] in the placebo group). Urticaria was reported by 5 participants who received mRNA-1273 and 2 participants who received placebo (< 0.1% each); no other unsolicited TEAE (PT) leading to discontinuation from the study vaccine was reported by more than 3 participants in either group.

The participant incidence of unsolicited TEAEs leading to discontinuation from participation in the study up to 28 days after any injection was similar between the mRNA-1273 group (< 0.1%; 9 events) and the placebo group (< 0.1%; 6 events) (Table 7-25). No unsolicited TEAE (PT) leading to discontinuation from participation in the study up to 28 days after any injection was reported by more than 1 participant in either group.

The participant incidence of unsolicited TEAEs leading to discontinuation from participation in Part A was similar between the mRNA-1273 group (0.2%; 26 events) and the placebo group (0.2%; 23 events) (Table 14.3.1.16.1.3). Myocardial infarction was reported by 2 participants in the mRNA-1273 group and 4 participants in the placebo group, and COVID-19 was reported in 1 participant in the mRNA-1273 group and 3 participants in the placebo group (< 0.1% each); no other unsolicited TEAE (PT) leading to discontinuation from participation in the study was reported by more than 2 participants in either group. In addition, events coded as “death” without further specification were reported for 4 participants in the mRNA-1273 group and 2 participants in the placebo group (Section 7.3.1).

Case narratives for participants with AEs leading to discontinuation from the study are provided in Section 15.

Table 7-24: Participant Incidence of Unsolicited Treatment-Emergent Adverse Event Leading to Discontinuation from Study Vaccine by System Organ Class and Preferred Term (Safety Set)

System Organ Class Preferred Term	Placebo (N=15162) n (%)	mRNA-1273 (N=15184) n (%)	Rate Ratio (95% CI)	Total (N=30346) n (%)

A treatment-emergent adverse event (TEAE) is defined as any event not present before exposure to study vaccination or any event already present that worsens in intensity or frequency after exposure.

Percentages are based on the number of safety subjects. Percentages are based on the number of safety subjects. The rate ratio is calculated as the ratio of percentage of participants reporting the event in mRNA-1273 divided by that in Placebo; rate ratio is provided for TEAEs with at least 7 subjects in any vaccination group reporting the event. The 95% CI is calculated using the Miettinen and Nurminen method.

Source: Table 14.3.1.16.1.1.

7.3.3.2 Medically Attended Treatment-Emergent Adverse Events

Data summarized for Part A include all available participant level data up to early unblinding, study discontinuation, the Part B PDV or data cutoff date (26 Mar 2021), whichever was earlier; the longer follow-up duration allowed more events to accumulate compared with the 28-day follow-up period.

In Part A, the participant incidence of unsolicited MAAEs was balanced between the mRNA-1273 and placebo groups (22.8% and 27.2%, respectively), with 6145 events reported in the mRNA-1273 group and 7272 events reported in the placebo group (Table 7-26). COVID-19 was the most common MAAE and was reported more frequently in the placebo group (5.9%) than in the mRNA-1273 group (0.5%). The incidence of other most common (≥ 1.0% in either group) MAAEs was balanced between the groups: upper respiratory tract infection (1.2% mRNA-1273 vs. 1.4% placebo); urinary tract infection (0.9% mRNA-1273 vs. 1.2% placebo); and hypertension (1.2% mRNA-1273 vs. 1.4% placebo).

Rate ratios were provided for events (preferred terms) that were reported for at least 7 participants in any treatment group. Events for which the 95% CI for the ratio excludes 1 were as follows (rate ratio [95% CI] for mRNA-1273 > placebo participants): herpes zoster (2.35 [1.34, 4.11]), enterovirus infection (4.99 [1.23, 20.26]), cervical radiculopathy (11.98 [2.00, 71.83]), and facial bones fracture (7.99 [1.30, 49.20]). Assessment of notable imbalances for herpes zoster, cervical radiculopathy, and facial bones fracture is provided in Section 7.2.2. Please note that because the study was not designed to evaluate for differences in the incidences of rare events, nor was any multiplicity adjustment made, the results of these statistical comparisons should be interpreted with caution.

In the 28-day follow-up period, the participant incidence of unsolicited MAAEs was balanced between the mRNA-1273 and placebo groups (12.0% and 12.8%, respectively), with 2715 events reported in the mRNA-1273 group and 2863 events reported in the placebo group (Table 14.3.1.19.1.1). COVID-19 was reported more frequently in the placebo group (0.9%) than in the mRNA-1273 group (0.1%).

Table 7-26: Participant Incidence of Unsolicited Medically-Attended Treatment-Emergent Adverse Event (at Least 5 Participants in Any Group Based on Preferred Term) by System Organ Class and Preferred Term in Part A (Safety Set)

System Organ Class Preferred Term	Placebo (N=15162) n (%)	mRNA-1273 (N=15184) n (%)	Rate Ratio (95% CI)	Total (N=30346) n (%)
Number of subjects reporting unsolicited adverse events	4131 (27.2)	3468 (22.8)		7599 (25.0)

A treatment-emergent adverse event (TEAE) is defined as any event not present before exposure to study vaccination or any event already present that worsens in intensity or frequency after exposure.

Percentages are based on the number of safety subjects. The rate ratio is calculated as the ratio of percentage of participants reporting the event in mRNA-1273 divided by that in Placebo; rate ratio is provided for TEAEs with at least 7 subjects in any vaccination group reporting the event. The 95% CI is calculated using the Miettinen and Nurminen method.

MedDRA version 23.0.

7.3.3.3 Analysis of Adverse Events of Clinical Interest

Analyses for AEs of clinical interest were performed by searching the database using Standardized MedDRA Queries (SMQs) or Custom MedDRA Queries (CMQs). The SMQs for this study were anaphylactic reaction (Table 14.3.1.22.8), angioedema (Table 14.3.1.22.4), arthritis (Table 14.3.1.22.3), cardiomyopathy (Table 14.3.1.22.16), CNS vascular disorders (Section 7.3.3.3.4, Table 14.3.1.22.10), convulsions (Table 14.3.1.22.7), demyelination (Table 14.3.1.22.6), embolic and thrombotic events (Table 14.3.1.22.12), hearing and vestibular disorders (Table 14.3.1.22.13), hematopoietic cytopenias (Section 7.3.3.3.5, Table 14.3.1.22.15), hypersensitivity (Section 7.3.3.3.1, Table 14.3.1.22.2), peripheral neuropathy (Table 14.3.1.22.5), thrombophlebitis (Table 14.3.1.22.14), and vasculitis (Table 14.3.1.22.1). The CMQs were autoimmune disorders (Table 14.3.1.22.9) and dermal filler reaction post vaccination (Section 7.3.3.3.2, Table 14.3.1.22.11). The SMQ and CMQ analyses for which potential imbalances were observed are described in subsections below. Terms included in the SMQs and CMQs are provided in Appendix 16.1.13 (narrow scope terms are summarized in this report).

7.3.3.3.1 Hypersensitivity

A total of 614 participants (2.0%) reported at least one hypersensitivity event (336 participants [2.2%] in the mRNA-1273 group and 278 participants [1.8%] in the placebo group) (Table 14.3.1.22.2). Hypersensitivity events for which larger imbalances between the groups were observed were consistent with the known reactogenicity of the vaccine. Injection site urticaria was reported by 38 participants (0.3%) overall in the mRNA-1273 group vs. 1 participant (< 0.1%) in the placebo group; this imbalance was noted in the older age group but not in the younger age group. Injection site rash was reported by 25 participants [0.2%] overall in the mRNA-1273 group vs. 1 participant (< 0.1%) in the placebo group; this imbalance was noted the younger age group but not in the older age group; Table 14.3.1.22.2). No imbalance was apparent for events in the angioedema SMQ (82 vs. 71 participants [0.5% for each] in the mRNA-1273 and placebo groups, respectively [Table 14.3.1.22.4)].

7.3.3.3.2 Anaphylaxis

In the anaphylaxis SMQ, 9 events were reported for 5 participants in the mRNA-1273 group and 18 events were reported for 8 participants in the placebo group (Table 14.3.1.22.8). Anaphylactic reaction was reported in 2 participants in the placebo group on Days 11 and 10 after the first injection; one event was severe and one was grade 4 in severity; both were considered not related to IP and resolved on the same day with concomitant medications. Anaphylactic reaction of unknown cause was reported for 2 participants in the mRNA-1273 group as nonserious moderate events approximately 2 months after the second dose; both were considered not related to IP and

resolved on the same day with concomitant medications. Among the other terms in the SMQ, reported events in the mRNA-1273 group were all nonserious and described as follows: mild cough and mild eye pruritus for one participant on Day 47 after the second dose (not considered related); mild tachypnea on Day 29 after the first dose (which was reported on the day of the second dose), severe tachypnea on Day 1 after the second dose (which was the same day; event resolved on Day 64), and moderate urticaria beginning 30 minutes after the second dose and resolved in 1 hour with concomitant medication (all events considered related); and moderate dyspnea (considered related; reported as resolving) and severe swelling face (not considered related; resolving with prednisone) beginning on Day 34 after the second dose (Listing 16.2.7.28). Events in the placebo group were also nonserious and included hypotension and cough; dyspnea, hypotension, and edema; dyspnea and pruritus; hypotension and wheezing; urticaria and asthma; tachypnea (participant later had grade 4 serious anaphylactic reaction); and asthma.

7.3.3.3.3 Dermal Filler Reaction Post Vaccination

A total of 34 participants (0.1%) reported at least one TEAE in the dermal filler post-vaccination CMQ (20 participants [0.1%] in the mRNA-1273 group and 14 participants [< 0.1%] in the placebo group) and no imbalance was apparent for any individual PT (Table 14.3.1.22.11). The event was reported as an SAE for 2 participants in the mRNA-1273 group and 1 participant in the placebo group (Section 7.3.2). The event was considered related to treatment for 4 participants in the mRNA-1273 group and 3 participants in the placebo group. None of the participants who experienced this TEAE in this study had reported dermal filler reaction post vaccination in their medical history. History of dermal filler use was reported for 325 participants in the mRNA-1273 group and 234 participants in the placebo group.

7.3.3.3.4 Central Nervous System Vascular Disorders

A total of 32 participants (0.1%) experienced at least one TEAE in the CNS vascular disorders SMQ (21 participants [0.1%] in the mRNA-1273 group and 11 participants [< 0.1%] in the placebo group) (Table 14.3.1.22.10). The following events were reported for more participants in the mRNA-1273 group than in the placebo group: cerebrovascular accident (7 vs. 4), carotid artery stenosis (2 vs. 0), and embolic stroke (2 vs. 0). Further discussion of these types of events is provided in Section 7.3.2. No cases of thrombosis with thrombocytopenia syndrome were reported. For all events in the category, the difference between the mRNA-1273 and placebo groups was more pronounced among participants ≥ 65 years of age (11 vs. 4) than among participants ≥ 18 to < 65 years of age (10 vs. 7). The age distribution and the overall incidence in the mRNA-1273 group is consistent with general epidemiology of these types of vascular events, and the timing of the events is also not consistent with an attribution to mRNA-1273. Imbalances

were also noted for subarachnoid hemorrhage (4 vs. 0) and subdural hematoma (3 vs. 0), but these events were related to trauma (with precipitating events not considered related to mRNA-1273) and are thus not indicative of a vascular disorder (Section 7.3.2).

7.3.3.3.5 Hematopoietic Cytopenias

Thrombocytopenia was reported for 5 participants in the mRNA-1273 group and 1 participant in the placebo group (Table 14.3.1.22.15); these events were not associated with thrombosis and none were considered related to IP. One participant in each group had an SAE of grade 4 thrombocytopenia: the event occurred on Day 68 (approximately 40 days after the second dose) for the participant in the mRNA-1273 group [US3912024]. At the same time, the participant (who was 72 years old) had severe bacterial pyelonephritis, acute kidney failure (SAE), and nephrolithiasis (SAE). The event occurred on Day 131 for the participant in the placebo group [US3272026], who also had COVID-19 infection and cytokine storm and several other grade 4 SAEs. The nonserious thrombocytopenia TEAEs in the mRNA-1273 group were all mild and occurred on Days 25, 57, 60 (concurrent with moderate periorbital hematoma, mild periorbital hemorrhage, grade 4 serious alcohol withdrawal syndrome, and multiple other events [US3062265]), and 153. No imbalance was evident for the other terms included in the SMQ for hematopoietic cytopenias.

7.3.3.4 Vaccine-Associated Enhanced Respiratory Disease

The DSMB continuously monitored case counts of COVID-19 and severe COVID-19 based on prespecified criteria for any indication of higher disease incidence and/or severity in the mRNA-1273 group compared with the placebo group that might suggest a risk of vaccine harm in the form of vaccine-associated enhanced respiratory disease (VAERD) (Section 4.2.3.5). The prespecified criteria for enhanced disease have not been met at any time during the study. Fewer cases of severe COVID-19 (Table 6-4) or COVID-19 of any severity (Table 6-2) have been observed in participants who received mRNA-1273 than in those who received placebo. Instead of enhanced disease, participants who received mRNA-1273 and experienced COVID-19 had milder disease compared with those who received placebo (based on symptom scores during the 28 days after onset; Section 6.3.1).

7.3.4 Subgroup Analyses of Deaths, Other Serious Adverse Events, and Other Significant Unsolicited Adverse Events

7.3.4.1 Age Groups

The overall incidence of serious TEAEs in Part A was higher in older adults (≥ 65 years of age) compared to younger adults (18 to < 65 years of age) who received either mRNA-1273

(118/3769 [3.1%] vs.150/11415 [1.3%]) or placebo (124/3751 [3.3%] vs.168/11411 [1.5%]; Table 7-27). The overall incidence of serious treatment-related TEAEs in Part A were low and comparable at <0.1% for younger adults (18 to < 65 years of age) and older adults (≥ 65 years of age) who received either mRNA-1273 or placebo (Table 14.3.1.14.2.1).

Table 7-27: Participant Incidence of Serious Treatment-Emergent Adverse Events by Age Group, System Organ Class and Preferred Term in Part A (Safety Set)

System Organ Class Preferred Term	Placebo (N=11411) n (%)	mRNA-1273 (N=11415) n (%)	Rate Ratio (95% CI)	Total (N=22826) n (%)
Age Group: >=18 and <65 Years				
Number of subjects reporting unsolicited adverse events	168 (1.5)	150 (1.3)		318 (1.4)
Number of unsolicited adverse events	257	216		473
Infections and infestations	41 (0.4)	30 (0.3)		71 (0.3)

A treatment-emergent adverse event (TEAE) is defined as any event not present before exposure to study vaccination or any event already present that worsens in intensity or frequency after exposure.

Percentages are based on the number of safety subjects. The rate ratio is calculated as the ratio of percentage of participants reporting the event in mRNA-1273 divided by that in Placebo; rate ratio is provided for TEAEs with at least 7 subjects in any vaccination group reporting the event. The 95% CI is calculated using the Miettinen and Nurminen method.

MedDRA version 23.0.

Source: Table 14.3.1.13.2.3.

7.3.4.2 Baseline SARS-CoV-2 Status

The overall incidence of serious treatment-related TEAEs in Part A were low and comparable at <0.1% for participants with a negative Baseline SARS-CoV-2 status who received either mRNA-1273 or placebo (Table 14.3.1.14.3.3). No serious TEAEs assessed as treatment-related were reported in participant with a positive Baseline SARS-CoV-2 status.

7.4 Clinical Laboratory Evaluation

Clinical laboratory assessments were not planned or performed.

7.5 Vital Signs and Other Observations Related to Safety

Mean vital sign measurements (diastolic blood pressure, pulse rate, respiratory rate, systolic blood pressure, and temperature) observed after dosing and through Day 209 were comparable to those observed at baseline, with no notable trends or differences across groups (Table 14.3.2.1).

The incidence of shifts from baseline to worst postbaseline for all vital sign measurements (diastolic blood pressure, pulse rate, respiratory rate, systolic blood pressure, and temperature) were comparable between the mRNA-1273 and placebo groups, with no notable trends or differences across groups (Table 14.3.2.2).

7.6 Pregnancies

As of the date of the data cutoff for this CSR, there were 9 participants (4 in the mRNA-1273 group and 5 in the placebo group) with positive results for urine pregnancy tests performed at the site during Part A (Listing 16.2.8).

According to the safety database, a total of 27 pregnancies were reported (16 in the mRNA-1273 group and 11 in the placebo group) during Part A of the study (Table 7-28). Of the outcomes known as of 04 May 2021, 1 participant in the placebo group experienced a live birth. The participant was induced at 37 weeks due to polyhydramnios and gestational diabetes and the child was noted as having congenital anomalies of bilateral talipes equinovarus and hydronephrosis. Five participants (2 in the mRNA-1273 group and 3 in the placebo group) experienced spontaneous abortion/miscarriage. These events were reported as SAEs for 4 of the participants (2 participants in each group) and were considered not related to IP; for 1 participant in the placebo group, the event was considered nonserious and causality was not reported. Two participants (1 in each group) underwent elective termination of pregnancy; there were no reported pregnancy complications for either participant.

Case narratives for the participants who experienced pregnancies are provided in Section 15.

Table 7-28: Incidence of Pregnancies Reported in Part A and Outcomes (Safety Set)

	Placebo	mRNA-1273	Total
Number of pregnancies	11	16	27
Known pregnancy outcomes	5	3	8
Live born	1[a, b]	0	1
Spontaneous abortion/miscarriage	3	2[c]	5
Elective termination	1	1	2[d]
Other maternal/gestational complications	1[a, b]	0	1
Lost to follow-up	2[e, f]	1[e]	3

[a] Baby was born at 37 weeks with congenital anomalies of bilateral talipes equinovarus and hydronephrosis.

[b] The mother of the baby with talipes equinovarus and hydronephrosis had polyhydramnios and gestational diabetes.

[c] The outcome of spontaneous abortion/miscarriage for 1 participant occurred after the Participant Decision Visit and is therefore reported as an serious adverse event in the Part B addendum to this Clinical Study Report.

[d] There were no reported pregnancy complications in either group.

[e] No response to follow up requests in 1 subject in each group with expected dates of delivery prior to data cut off of 04 May 2021.

[f] One subject was categorized as study lost to follow-up.

Source: Data in the table was generated from the safety database and case narratives for the participants who experienced pregnancies are provided in Section 15.

7.7 Safety Conclusions

In this final, randomized, blinded phase (Part A) analysis, the mRNA-1273 vaccine administered as 2 injections 28 days apart demonstrated an acceptable safety profile in the study population. This conclusion is supported by reactogenicity and key safety findings summarized here.

Solicited local and systemic adverse reactions were more frequent in mRNA-1273 than in placebo recipients, with most events considered grade 1 or 2 in severity, and most events in mRNA-1273 recipients occurring within 1 to 2 days and lasting a median of 1 to 3 days. The most common solicited local AR was pain, and the most commonly reported solicited systemic ARs were fatigue, headache, myalgia, and arthralgia. Older adults (≥ 65 years) had lower rates of solicited ARs than younger adults (< 65 years). Participants SARS-CoV-2 positive at baseline had rates of solicited ARs comparable to those among baseline negative participants. More mRNA-1273 recipients reported use of medication for pain or fever than placebo recipients, consistent with vaccine reactogenicity.

Unsolicited TEAEs in the 28 days after any injection occurred at similar rates in the mRNA-1273 and placebo groups. The higher rate of unsolicited TEAEs considered treatment related by the investigator among mRNA-1273 participants was largely driven by events that mapped to solicited ARs but occurred beyond the solicited AR collection period or were ARs similar to solicited ARs. In addition, TEAEs were assessed for: (i) imbalances between study groups, and

(ii) AEs of interest following COVID-19 vaccination or vaccinations in general. Imbalances were investigated based on the degree of imbalance and the biological plausibility and temporal occurrence relative to study treatment. An imbalance in the overall number of herpes zoster cases was noted, with more cases in the mRNA-1273 than in the placebo group; however, most cases in the mRNA-1273 group occurred more than 28 days after any dose and at an incidence expected in the general population. In contrast, most cases in the placebo group occurred within 28 days and at rates lower than expected of the general population. These findings are not supportive of relatedness to mRNA-1273.

Certain AEs are of theoretical interest for COVID-19 vaccines and were carefully assessed in the blinded study phase. As noted in Section 6, mRNA-1273 vaccine was highly efficacious in preventing COVID-19 and severe COVID-19, and this efficacy has been sustained, dispelling concerns of VAERD. No significant clinical findings were identified from the SMQ/CMQ searches performed for the analyses of AEs of clinical interest for COVID-19 vaccines. A search (SMQ) for CNS vascular disorders identified a categorical imbalance, with 21 participants in the mRNA-1273 and 11 participants in the placebo group experiencing events in this SMQ, but the apparent imbalance was largely due to inclusion of 5 participants with subarachnoid hemorrhage and subdural hematoma (3 and 2 participants, respectively in the mRNA-1273 group and none in placebo) in this category. These latter events were mostly related to trauma and not to study treatment. Other events of potential interest for COVID-19 vaccines are thrombotic and embolic events, for which no imbalance between groups was identified. Finally, assessments for TEAEs of myocarditis or pericarditis, or the symptoms suggestive of these diagnoses (including chest pain, dyspnea, and tachycardia) was performed. No events of myocarditis were identified. Pericarditis without concurrent myocarditis was reported as an SAE for 2 participants in each treatment group; the 2 events in the mRNA-1273 group occurred more than 28 days after second dose and in participants older than 55 years. Symptoms consistent with myocarditis or pericarditis were assessed, seeking patterns in grouping of symptoms or clustering in time, and only a single participant met a diagnosis of pericarditis. Assessment of events often associated with vaccination was performed, with a focus on hypersensitivity and anaphylaxis. Hypersensitivity events were more common among mRNA-1273 than placebo recipients; most of the imbalance derived from injection site urticaria and rashes. No anaphylaxis events were reported within 30 minutes after any injection.

In total, mRNA-1273 has a reactogenicity profile consistent with parenteral vaccination and generally well-tolerated. Similarly, the safety profile is acceptable. No unexpected findings were identified in this final assessment of the randomized, blinded phase of the study.

12 STUDY CONCLUSIONS

This study was designed to evaluate the efficacy, safety, and immunogenicity of mRNA-1273 SARS-CoV-2 vaccine compared to placebo in adults 18 years of age and older who have no known history of SARS-CoV-2 infection but whose occupation or location and living circumstances put them at increased risk of acquiring COVID-19 and/or SARS-CoV-2 infection.

- The final efficacy analysis of the primary endpoint for Part A (04 May 2021) included 799 cases. The results of this analysis were consistent with the results of the interim and primary efficacy analysis, confirming persistent, high efficacy over a substantially larger case database and over a longer median observation period of over 5.3 months. For the final efficacy analysis, the VE point estimate was 93.2% ($p < 0.0001$) and within the 95% CIs of the VE point estimates for the interim and primary efficacy analyses.
    - Divergence of case incidence began early between mRNA-1273 and placebo groups, starting in the period from randomization up to 14 days after the first injection. Thereafter, cumulative incidence rate for the placebo group increased steadily while it remained stable and low in the mRNA-1273 group for the remainder of the observation period.
    - Vaccine efficacy was consistent across subgroups for the primary efficacy endpoint.
    - Vaccine efficacy was also consistent across the secondary endpoints characterized by high VE point estimates and tight 95% CIs, with the lower bounds of the 95% CIs well above 30%.
- mRNA-1273 was highly immunogenic as measured by both bAb and nAb in both SARS-CoV-2 baseline-negative and baseline-positive individuals, as indicated by increased bAb and nAb levels 1 month after first injection (Day 29) and 1 month after second injection (Day 57).
- mRNA-1273 demonstrated an acceptable safety profile in the participant population enrolled in this study. mRNA-1273 has a reactogenicity profile consistent with parenteral vaccination and generally well tolerated. No unexpected findings were identified in this final assessment of the randomized, blinded phase of the study.

This report is based on the data from the randomized, placebo controlled, blinded phase (Part A) of the study. Data from Part B, in which eligible participants were offered open-label mRNA-1273, will be included in a CSR addendum.

Table 14.1.3.1.1
Baseline Demographics and Characteristics by Baseline SARS-CoV-2 Status
Full Analysis Set

Percentages are based on the number of subjects in Full Analysis Set.
[1] Based on stratification factor from IRT, subjects who are < 65 years old are categorized as at risk for severe COVID-19 illness if they have at least 1 of the risk factors specified in the study protocol at Screening.
[2] Subjects could be under one or more categories, and are counted once at each category.
[3] Age and health risk for severe COVID-19 are derived from age and risk factors collected on case report form (CRF).
[4] Baseline SARS-CoV-2 Status: Positive if there is immunologic or virologic evidence of prior COVID-19, defined as positive RT-PCR test or positive Elecsys result at Day 1. Negative is defined as negative RT-PCR test and negative Elecsys result at Day 1.
[5] Minority is defined as Blacks or African Americans, Hispanics or Latinos, American Indians or Alaska Natives, Native Hawaiians, and other Pacific Islanders, and Non-Minority includes all the others whose race or ethnicity is not unknown, unreported or missing.
[6] White is defined as White and non-Hispanic, and Communities of Color includes all the others whose race or ethnicity is not unknown, unreported or missing.

Table 14.1.3.1.2
Baseline Demographics and Characteristics by Age Group
Full Analysis Set

Percentages are based on the number of subjects in Full Analysis Set.
[1] Based on stratification factor from IRT, subjects who are < 65 years old are categorized as at risk for severe COVID-19 illness if they have at least 1 of the risk factors specified in the study protocol at Screening.
[2] Subjects could be under one or more categories, and are counted once at each category.
[3] Age and health risk for severe COVID-19 are derived from age and risk factors collected on case report form (CRF).
[4] Baseline SARS-CoV-2 Status: Positive if there is immunologic or virologic evidence of prior COVID-19, defined as positive RT-PCR test or positive Elecsys result at Day 1. Negative is defined as negative RT-PCR test and negative Elecsys result at Day 1.
[5] Minority is defined as: Blacks or African Americans, Hispanics or Latinos, American Indians or Alaska Natives, Native Hawaiians, and other Pacific Islanders, and Non-Minority includes all the others whose race or ethnicity is not unknown, unreported or missing.
[6] White is defined as White and non-Hispanic, and Communities of Color includes all the others whose race or ethnicity is not unknown, unreported or missing.

Table 14.1.3.1.3
Baseline Demographics and Characteristics by Randomization Stratum
Full Analysis Set

Percentages are based on the number of subjects in Full Analysis Set.
[1] Based on stratification factor from IRT, subjects who are < 65 years old are categorized as at risk for severe COVID-19 illness if they have at least 1 of the risk factors specified in the study protocol at Screening.
[2] Subjects could be under one or more categories, and are counted once at each category.
[3] Age and health risk for severe COVID-19 are derived from age and risk factors collected on case report form (CRF).
[4] Baseline SARS-CoV-2 Status: Positive if there is immunologic or virologic evidence of prior COVID-19, defined as positive RT-PCR test or positive Elecsys result at Day 1. Negative is defined as negative RT-PCR test and negative Elecsys result at Day 1.
[5] Minority is defined as: Blacks or African Americans, Hispanics or Latinos, American Indians or Alaska Natives, Native Hawaiians, and other Pacific Islanders, and Non-Minority includes all the others whose race or ethnicity is not unknown, unreported or missing.
[6] White is defined as White and non-Hispanic, and Communities of Color includes all the others whose race or ethnicity is not unknown, unreported or missing.

Table 14.1.3.2.1
Baseline Demographics and Characteristics by Baseline SARS-CoV-2 Status
Safety Set

Percentages are based on the number of safety subjects.
[1] Based on stratification factor from IRT, subjects who are < 65 years old are categorized as at risk for severe COVID-19 illness if they have at least 1 of the risk factors specified in the study protocol at Screening.
[2] Subjects could be under one or more categories, and are counted once at each category.
[3] Age and health risk for severe COVID-19 are derived from age and risk factors collected on case report form (CRF).
[4] Baseline SARS-CoV-2 Status: Positive if there is immunologic or virologic evidence of prior COVID-19, defined as positive RT-PCR test or positive Elecsys result at Day 1. Negative is defined as negative RT-PCR test and negative Elecsys result at Day 1.
[5] Minority is defined as: Blacks or African Americans, Hispanics or Latinos, American Indians or Alaska Natives, Native Hawaiians, and other Pacific Islanders, and Non-Minority includes all the others whose race or ethnicity is not unknown, unreported or missing.
[6] White is defined as White and non-Hispanic, and Communities of Color includes all the others whose race or ethnicity is not unknown, unreported or missing.

Table 14.1.3.2.2
Baseline Demographics and Characteristics by Age Group
Safety Set

Percentages are based on the number of safety subjects.
[1] Based on stratification factor from IRT, subjects who are < 65 years old are categorized as at risk for severe COVID-19 illness if they have at least 1 of the risk factors specified in the study protocol at Screening.
[2] Subjects could be under one or more categories, and are counted once at each category.
[3] Age and health risk for severe COVID-19 are derived from age and risk factors collected on case report form (CRF).
[4] Baseline SARS-CoV-2 Status: Positive if there is immunologic or virologic evidence of prior COVID-19, defined as positive RT-PCR test or positive Elecsys result at Day 1. Negative is defined as negative RT-PCR test and negative Elecsys result at Day 1.
[5] Minority is defined as: Blacks or African Americans, Hispanics or Latinos, American Indians or Alaska Natives, Native Hawaiians, and other Pacific Islanders, and Non-Minority includes all the others whose race or ethnicity is not unknown, unreported or missing.
[6] White is defined as White and non-Hispanic, and Communities of Color includes all the others whose race or ethnicity is not unknown, unreported or missing.

Table 14.1.3.2.3
Baseline Demographics and Characteristics by Randomization Stratum
Safety Set

Percentages are based on the number of safety subjects.
[1] Based on stratification factor from IRT, subjects who are < 65 years old are categorized as at risk for severe COVID-19 illness if they have at least 1 of the risk factors specified in the study protocol at Screening.
[2] Subjects could be under one or more categories, and are counted once at each category.
[3] Age and health risk for severe COVID-19 are derived from age and risk factors collected on case report form (CRF).
[4] Baseline SARS-CoV-2 Status: Positive if there is immunologic or virologic evidence of prior COVID-19, defined as positive RT-PCR test or positive Elecsys result at Day 1. Negative is defined as negative RT-PCR test and negative Elecsys result at Day 1.
[5] Minority is defined as: Blacks or African Americans, Hispanics or Latinos, American Indians or Alaska Natives, Native Hawaiians, and other Pacific Islanders, and Non-Minority includes all the others whose race or ethnicity is not unknown, unreported or missing.
[6] White is defined as White and non-Hispanic, and Communities of Color includes all the others whose race or ethnicity is not unknown, unreported or missing.

Table 14.1.3.2.4
Baseline Demographics and Characteristics by Age Group (>=18 and <=25, >=26 and <=50)
Safety Set — Subjects with Age >=18 and <=50 Years

Percentages are based on the number of safety subjects.
[1] Based on stratification factor from IRT, subjects who are < 65 years old are categorized as at risk for severe COVID-19 illness if they have at least 1 of the risk factors specified in the study protocol at Screening.
[2] Subjects could be under one or more categories, and are counted once at each category.
[3] Age and health risk for severe COVID-19 are derived from age and risk factors collected on case report form (CRF).
[4] Baseline SARS-CoV-2 Status: Positive if there is immunologic or virologic evidence of prior COVID-19, defined as positive RT-PCR test or positive Elecsys result at Day 1. Negative is defined as negative RT-PCR test and negative Elecsys result at Day 1.
[5] Minority is defined as: Blacks or African Americans, Hispanics or Latinos, American Indians or Alaska Natives, Native Hawaiians, and other Pacific Islanders, and Non-Minority includes all the others whose race or ethnicity is not unknown, unreported or missing.
[6] White is defined as White and non-Hispanic, and Communities of Color includes all the others whose race or ethnicity is not unknown, unreported or missing.

Table 14.1.3.3.2
Baseline Demographics and Characteristics by Age Group
mITT Set

Percentages are based on the number of subjects in mITT set.
[1] Based on stratification factor from IRT, subjects who are < 65 years old are categorized as at risk for severe COVID-19 illness if they have at least 1 of the risk factors specified in the study protocol at Screening.
[2] Subjects could be under one or more categories, and are counted once at each category.
[3] Age and health risk for severe COVID-19 are derived from age and risk factors collected on case report form (CRF).
[4] Baseline SARS-CoV-2 Status: Positive if there is immunologic or virologic evidence of prior COVID-19, defined as positive RT-PCR test or positive Elecsys result at Day 1. Negative is defined as negative RT-PCR test and negative Elecsys result at Day 1.
[5] Minority is defined as: Blacks or African Americans, Hispanics or Latinos, American Indians or Alaska Natives, Native Hawaiians, and other Pacific Islanders, and Non-Minority includes all the others whose race or ethnicity is not unknown, unreported or missing.
[6] White is defined as White and non-Hispanic, and Communities of Color includes all the others whose race or ethnicity is not unknown, unreported or missing.

Table 14.1.3.3.3
Baseline Demographics and Characteristics by Randomization Stratum
mITT Set

Percentages are based on the number of subjects in mITT set.
[1] Based on stratification factor from IRT, subjects who are < 65 years old are categorized as at risk for severe COVID-19 illness if they have at least 1 of the risk factors specified in the study protocol at Screening.
[2] Subjects could be under one or more categories, and are counted once at each category.
[3] Age and health risk for severe COVID-19 are derived from age and risk factors collected on case report form (CRF).
[4] Baseline SARS-CoV-2 Status: Positive if there is immunologic or virologic evidence of prior COVID-19, defined as positive RT-PCR test or positive Elecsys result at Day 1. Negative is defined as negative RT-PCR test and negative Elecsys result at Day 1.
[5] Minority is defined as: Blacks or African Americans, Hispanics or Latinos, American Indians or Alaska Natives, Native Hawaiians, and other Pacific Islanders, and Non-Minority includes all the others whose race or ethnicity is not unknown, unreported or missing.
[6] White is defined as White and non-Hispanic, and Communities of Color includes all the others whose race or ethnicity is not unknown, unreported or missing.

Table 14.1.3.3.4
Baseline Demographics and Characteristics by Age Group
mITT Set — Subjects Only Received One Injection

Percentages are based on the number of subjects who only received one injection in mITT set.
[1] Based on stratification factor from IRT, subjects who are < 65 years old are categorized as at risk for severe COVID-19 illness if they have at least 1 of the risk factors specified in the study protocol at Screening.
[2] Subjects could be under one or more categories, and are counted once at each category.
[3] Age and health risk for severe COVID-19 are derived from age and risk factors collected on case report form (CRF).
[4] Baseline SARS-CoV-2 Status: Positive if there is immunologic or virologic evidence of prior COVID-19, defined as positive RT-PCR test or positive Elecsys result at Day 1. Negative is defined as negative RT-PCR test and negative Elecsys result at Day 1.
[5] Minority is defined as: Blacks or African Americans, Hispanics or Latinos, American Indians or Alaska Natives, Native Hawaiians, and other Pacific Islanders, and Non-Minority includes all the others whose race or ethnicity is not unknown, unreported or missing.
[6] White is defined as White and non-Hispanic, and Communities of Color includes all the others whose race or ethnicity is not unknown, unreported or missing.

Table 14.1.3.4.2
Baseline Demographics and Characteristics by Age Group
Per-Protocol Set

Percentages are based on the number of subjects in Per-Protocol Set.
[1] Based on stratification factor from IRT, subjects who are < 65 years old are categorized as at risk for severe COVID-19 illness if they have at least 1 of the risk factors specified in the study protocol at Screening.
[2] Subjects could be under one or more categories, and are counted once at each category.
[3] Age and health risk for severe COVID-19 are derived from age and risk factors collected on case report form (CRF).
[4] Baseline SARS-CoV-2 Status: Positive if there is immunologic or virologic evidence of prior COVID-19, defined as positive RT-PCR test or positive Elecsys result at Day 1. Negative is defined as negative RT-PCR test and negative Elecsys result at Day 1.
[5] Minority is defined as: Blacks or African Americans, Hispanics or Latinos, American Indians or Alaska Natives, Native Hawaiians, and other Pacific Islanders, and Non-Minority includes all the others whose race or ethnicity is not unknown, unreported or missing.
[6] White is defined as White and non-Hispanic, and Communities of Color includes all the others whose race or ethnicity is not unknown, unreported or missing.

Table 14.1.3.4.3
Baseline Demographics and Characteristics by Randomization Stratum
Per-Protocol Set

Percentages are based on the number of subjects in Per-Protocol Set.
[1] Based on stratification factor from IRT, subjects who are < 65 years old are categorized as at risk for severe COVID-19 illness if they have at least 1 of the risk factors specified in the study protocol at Screening.
[2] Subjects could be under one or more categories, and are counted once at each category.
[3] Age and health risk for severe COVID-19 are derived from age and risk factors collected on case report form (CRF).
[4] Baseline SARS-CoV-2 Status: Positive if there is immunologic or virologic evidence of prior COVID-19, defined as positive RT-PCR test or positive Elecsys result at Day 1. Negative is defined as negative RT-PCR test and negative Elecsys result at Day 1.
[5] Minority is defined as: Blacks or African Americans, Hispanics or Latinos, American Indians or Alaska Natives, Native Hawaiians, and other Pacific Islanders, and Non-Minority includes all the others whose race or ethnicity is not unknown, unreported or missing.
[6] White is defined as White and non-Hispanic, and Communities of Color includes all the others whose race or ethnicity is not unknown, unreported or missing.

Table 14.1.3.4.4
Baseline Demographics and Characteristics
Per-Protocol Set - Subjects with COVID-19* Based on Adjudication Committee Assessments Starting 14 Days After Second Injection

* with the censoring rules for efficacy analyses. COVID-19 case is based on eligible symptoms and positive RT-PCR within 14 days. If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys.
Percentages are based on the number of subjects in Per-Protocol Set with COVID-19 based on adjudication committee assessments starting 14 days after second injection.
[1] Based on stratification factor from IRT, subjects who are < 65 years old are categorized as at risk for severe COVID-19 illness if they have at least 1 of the risk factors specified in the study protocol at Screening.
[2] Subjects could be under one or more categories, and are counted once at each category.
[3] Age and health risk for severe COVID-19 are derived from age and risk factors collected on case report form (CRF).
[4] Baseline SARS-CoV-2 Status: Positive if there is immunologic or virologic evidence of prior COVID-19, defined as positive RT-PCR test or positive Elecsys result at Day 1. Negative is defined as negative RT-PCR test and negative Elecsys result at Day 1.
[5] Minority is defined as: Blacks or African Americans, Hispanics or Latinos, American Indians or Alaska Natives, Native Hawaiians, and other Pacific Islanders, and Non-Minority includes all the others whose race or ethnicity is not unknown, unreported or missing.
[6] White is defined as White and non-Hispanic, and Communities of Color includes all the others whose race or ethnicity is not unknown, unreported or missing.

<=3	0	0	0
>3 and <=7	0	0	0
>7	0	0	0

Percentages are based on the number of subjects in mITT Set.
* with the censoring rules for efficacy analyses. COVID-19 case is based on eligible symptoms and positive RT-PCR within 14 days. If a subject had positive RT-PCR at pre-dose 2 visit (Day 29) without eligible symptoms with 14 days, or positive Elecsys at scheduled visits prior to becoming a COVID-19 case, the subject is censored at the date with positive RT-PCR or Elecsys.
[1] COVID-19 cases based on adjudication committee assessments starting 14 days after second injection.
[2] Percentages are based on the number of subjects with adjudicated COVID-19 cases.

Figure 14.1.1.1 Discontinuation from Study by Month
Randomization Set

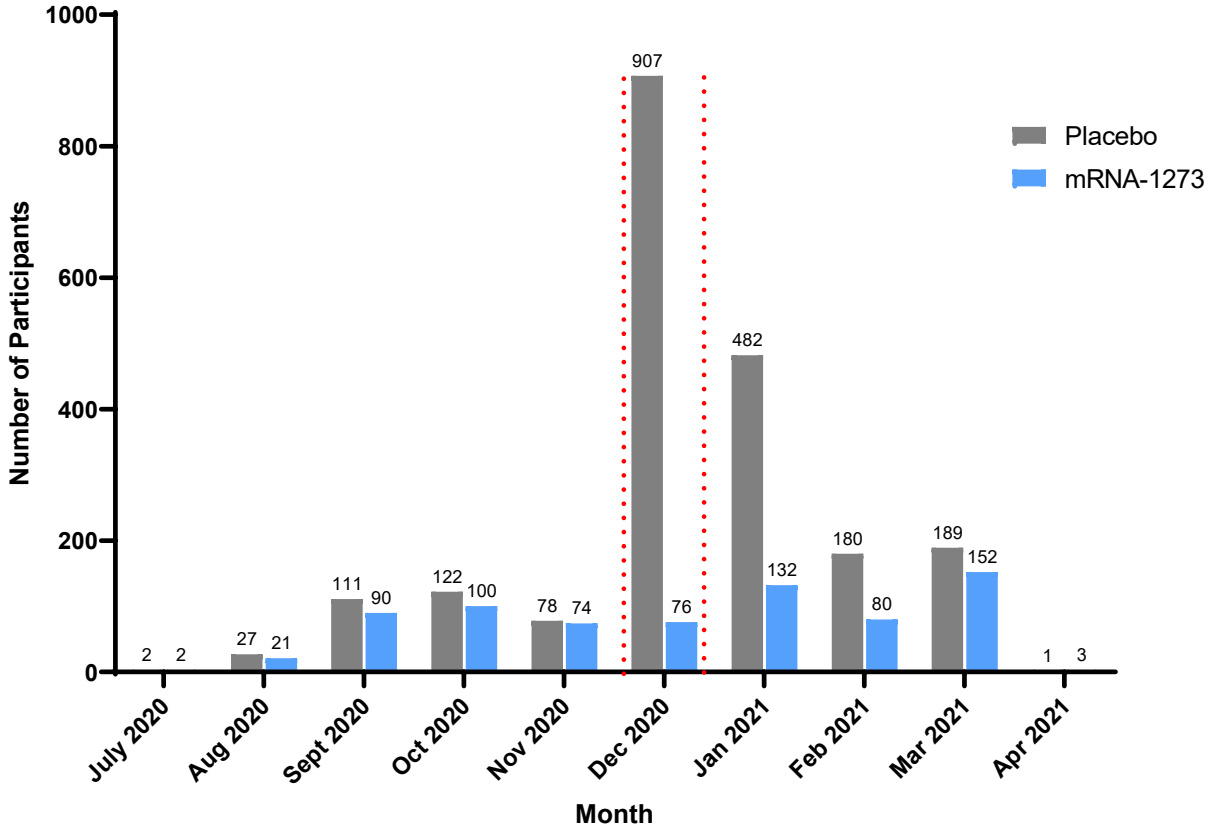

Table 14.2.2.1.1.1.1
Analysis of Vaccine Efficacy of mRNA-1273 to Prevent COVID-19 Based on Adjudication Committee Assessments Starting 14 Days After Second Injection
Per-Protocol Set

	Placebo (N=13883)	mRNA-1273 (N=13934)
Number of Subjects with COVID-19, n (%)	90 (0.6)	5 (<0.1)
Number of Subjects Censored, n (%)	13793 (99.4)	13929 (>99.9)
Vaccine Efficacy Based on Hazard Ratio (95% CI) [1]		0.945 (0.865, 0.978)
p-value [2]		<.0001
Person-Years [3]	2697.5	2716.9
Incidence Rate per 1,000 Person-Years (95% CI) [4]	33.365 (26.829, 41.011)	1.840 (0.598, 4.295)
Vaccine Efficacy Based on Incidence Rate (95% CI) [5]		0.945 (0.866, 0.983)

[1] Vaccine efficacy (VE), defined as 1 - hazard ratio (mRNA-1273 vs. placebo), and 95% CI are estimated using a stratified Cox proportional hazard model with Efron's method of tie handling and with the treatment group as a covariate, adjusting for stratification factor.
[2] 1-sided p-value from stratified Cox proportional hazard model to test the null hypothesis VE <= 0.3.
[3] Person-years is defined as the total years from randomization date to the date of COVID-19 or last date of study participation, whichever is earlier.
[4] Incidence rate is defined as the number of subjects with an event divided by the number of subjects at risk and adjusted by person-years (total time at risk) in each treatment group. The 95% CI is calculated using the exact method (Poisson distribution) and adjusted by person-years.
[5] VE is defined as 1 – ratio of incidence rate (mRNA-1273 vs. placebo). The 95% CI of the ratio is calculated using the exact method conditional upon the total number of cases, adjusting for person-years.
